BOULDER (origin obscure, usually compared with Sw. *bullersten*, a large rolling stone, so called from the noise with which it rolls, from *bullaa*, to thunder, roar), **ERRATIC**. A large mass of rock of rounded form found at a distance from the formation to which it belongs and lying detached on the surface or imbedded in the superficial deposits. Boulders originate, chiefly, either in corrosion by torrential waters or in erosion with solution along joint planes of rock and owe their present distribution to torrential waters, glacial ice, and icebergs. Boulders often furnish most beautifully preserved fossils, which cannot be collected from the more coherent portions of the parent ledge. From their magnitude and number they frequently give a striking expression to the landscape of the northern portion of the United States, especially in New England and Wisconsin. One at Nottingham, N. H., is estimated to weigh 6000 tons; another at Whitingham, Vt., weighs about 3000 tons. Large blocks of Scandinavian rock are scattered over the plains of Denmark, Prussia, and northern Germany. The pedestal of the statue of Peter the Great, in St. Petersburg, was hewn out of a large erratic boulder, 1500 tons in weight, that lay on a marshy plain near that city. See **BOULDER CLAY**; **GLACIER**; **GLACIAL PERIOD**; **GEOLOGY**.

BOULDER CLAY. A term applied to a deposit of compact blue or red clay occurring in the Glacial drift, and having boulders diffused throughout its mass, with here and there thin lenticular beds of gravel and sand interspersed. It is a very tough unwieldy material, sometimes more difficult to excavate than rock, and constitutes much of the hard pan under the soils of the northern States. It is found in many parts of the United States north of the terminal moraine of the continental ice sheet that existed in early Quaternary times. The boulders, which are the most striking feature of this bed, differ in size from small pebbles to masses many tons in weight. They are portions of rocks of all ages, more or less worn and often striated. The older rocks, when transported from a distance, are rounded, while those that have been derived from rocks in the neighboring districts are more angular. These masses are scattered without order in the clay, the heaviest blocks occurring frequently in the upper portions of the bed. The clay represents rock flour, produced by the grinding action of glaciers, aided by the harder rock fragments held in the ice. Layers of boulder clay vary in thickness, usually diminishing with the eleva-

tion of the point at which they are found. See **GLACIER**; **GLACIAL PERIOD**; **PLEISTOCENE PERIOD**.

BOULE, *βούλῆ* (Gk. *βούλη*, council). In ancient Greece, an advisory council. The *boule* of the Homeric times was composed of princes or leading men and was a purely consultative body, being convoked to assist the king in matters of public policy with information and advice. The Athenian *boule*, which was employed by Solon as a check on the *ecclesia* (*ἐκκλησία*), or popular assembly, was at first composed of 400 members, selected, in a manner not now ascertainable, but by election by the people, from the four tribes, 100 from each tribe, and from the three upper classes. Its duties were, properly, only to prepare matter for the discussions of the assembly, to convoke and superintend the meetings of the assembly, and to insure the execution of its decrees. The *boule* was thus, in effect, a committee of the popular assembly; in no sense was it comparable to the Roman Senate or to the Senate of an American State. The number of members of the *boule* was increased by Cleisthenes (508-507 B.C.) to 500, 50 members being taken from each of the 10 tribes into which the people were then divided; from this time its duties became more extensive, embracing matters of administration of revenue and general oversight. It made provision also for the maintenance of the navy and of the cavalry, tried cases of impeachment, received ambassadors, and introduced them to the *ecclesia*. From early in the fifth century all free-born Athenian citizens above 30 years of age were eligible to membership; they were thenceforth chosen by lot. At a still later time (306 B.C.) the number was further increased to 600, there being now 12 tribes, but in the time of Hadrian it was again reduced to 500. The meeting place of the *boule* was known as the *bouleuterion*. For the system whereby the *boule* met, not all at once, but by *prytanies*, see **ECCLÉSIA**. Consult: Schoemann, *Griechische Alterthümer*, 1^e, pp. 395 ff.; Hermann, *Griechische Staatsalterthümer*, sec. 128-127; Gilbert, *Griechische Staatsalterthümer*, 1², pp. 295 ff. (Eng. trans., pp. 265 ff.); Heydemann, *De Senatu Atheniensium* (Strassburg, 1880); Busolt, *Die Griechische Staats- und Rechtsalterthümer* (1902); J. E. Sandys, ed. of the *Constitution of Athens* (see **ARISTOTLE**).

BOULENGÉ (*βούλιν'ζαή'*) **CHRONOGRAPH**. See **BALLISTICS**.

BOULEUTERION. See **BOULE**.

BOULEVARD, *βούλ'ε-βάρ'*, or *βούλ'ε-βάρδ* (Fr. from Ger. *Bollwerk*, bulwark, bastion). A broad avenue, especially designed for promenades or driving, often lined with trees and sometimes parked or provided with trees, shrubs, and lawn. It was originally the rampart to a fortress or town. In European cities these ancient works have generally been leveled, the ditches filled up, and the space thus obtained employed for the formation of parks, promenades, and streets lined with trees. These, in France, still bear the name of boulevard. The boulevards of Paris are celebrated, and are of great service as open spaces promoting the circulation of air amidst the dense mass of habitations. Some parts of them present a bright and interesting spectacle; and as a whole, they afford a striking exhibition of the life and character of the French capital in all the different classes of society. The Thames Embankment is essentially a boulevard, formed by water-front improvement, in contrast

with the continental boulevards created on the site of abandoned fortifications. Many American cities have spent large sums of money in laying out spacious boulevards of considerable length. New York has a number of fine parkways or boulevards, especially in the boroughs of Brooklyn and Queens, and so have Boston, Chicago, and other American cities. It should be understood that the modern boulevard is really only a wider, handsomer, and more dignified street, or grand artery of travel, and that it may be radial, diagonal, or a part of a rectangular street system, as contrasted with the circumferential or ring-like boulevards which follow the sites of razed fortifications. See CITY PLANNING, STREETS

BOULGARIS See BULGARIS

BOULGER, bul'jer, GEORGE SIMONDS (1853-) An English botanist. He was born at Betchingley, Surrey, and was educated at Wellington and Epsom colleges. He was appointed professor of natural history at the Royal Agricultural College, Cirencester, in 1876, and professor of botany and geology at City of London College, in 1884. His publications include *Familiar Trees* (1886-89), *The Uses of Plants* (1889), *Biographical Index of British and Irish Botanists* (with J. Britten, 1893), *The Country Month by Month* (with J. A. Owen, 1894-95), *Elementary Geology* (1896), *Flowers of the Field* (1900, 33d ed, 1911), *Wood* (1902), *Botany* (1912), *Plant Geography* (1912).

BOULLE, bōl', or **BOULE** (formerly erroneously called Buhl) A family of distinguished French cabinetmakers—PIERRE (c 1580-1636), the eldest member of the family, emigrated from Neuchâtel to Paris, where he was employed by the King and had quarters in the Louvre. His sons Jacques and Paul followed their father's calling, but the most important member of the family was his nephew and pupil, **ANDRÉ CHARLES BOULLE** (1642-1732). He also had quarters in the Louvre, and, under the title of "marqueteur et ebeniste ordinaire du roi," enjoyed the special patronage of Louis XIV. Among his commissions for this monarch were various articles in the Queen's chamber and in the apartments of the Dauphin, Dauphine, Madame de Maintenon, and the Gallery des Glaces in the palace at Versailles, besides other work in the palace of St. Cloud. His masterpiece was the cabinet of the Dauphin, and his finest piece of furniture the marriage chests ordered by the King for this prince. Numerous examples of his art—tables, presses, writing desks, clocks, etc.—are preserved in the Louvre, the Garde-Meuble, Paris, the palaces of Versailles and Fontainebleau, the Musée Cluny, Paris, and in French and English private collections. In 1720 he had the misfortune to see all his precious models and designs destroyed by a fire which consumed his 20 workshops, and also his magnificent collection of paintings by old masters, drawings, and engravings. A poor business man, he was nearly always in debt.

André was not the inventor of the celebrated marquetry (qv) which bears his name, but he brought it to its highest perfection. It was a development of the intarsia (qv) of the Italian Renaissance. Through the skillful use of tortoise shell, copper, zinc, ivory, mother-of-pearl, etc., as inlay, endless variety of design and beauty of color were achieved—André's four sons, **JEAN PHILIPPE**, **PIERRE BENOÎT**, **CHARLES**

ANDRÉ, and **CHARLES JOSEPH**, continued their father's work, which is often difficult to distinguish from theirs. Like their father, they were usually in financial difficulties.

BOULOGNE, JEAN See BOLOGNA, GIOVANNI
BOULOGNE-SUR-MER, bōl'ōn'y'-sur-mär' (Fr. Boulogne on the sea, anciently, *Gesoriacum*, *Bononia*) A fortified seaport in the department of Pas-de-Calais, France (Map France, N, G 2). It stands at the mouth of the river Liane, on the English Channel, 22 miles southwest of Calais, and 139 miles north-northwest of Paris. The city is divided into the upper and lower, or the old and new districts. The upper city was once a great stronghold, and its ramparts are now spacious boulevards, commanding a fine marine view, with the coast of England as a horizon. At the east end stands an old castle with six turrets, which dates from 1231. In this part of the city are the fine Hôtel de Ville and the cathedral of Notre Dame, in Græco-Roman style, with a colossal statue of the Virgin surmounting the dome, which is 300 feet in height. The building was erected (1827-66) on the site of a Gothic cathedral destroyed in 1793. The lower or new town, with its broad, clean streets, is the centre of modern trade and social life. The beach affords good bathing and is very popular in summer. One of the chief objects of interest is the marble Column of the Grand Army, 176 feet high, surmounted by a bronze statue of Napoleon I, commemorating his projected invasion of England in 1804. In the lower town stand the barracks, the theatre, the museum of art, a hospital and a library. While the industries include the manufacture of steel pens, linen thread, carriages, glass, tubes, cement, etc., the main source of wealth of Boulogne is the sea, and the oyster, herring, cod, and mackerel fisheries. Its commerce consists chiefly in the importation of jute, wool, silk and woolen goods, skins, thread, coal, etc., and the exportation of wines, fruits, vegetables, cement, etc. Boulogne is one of the most frequented terminals of steamer routes from England, and a large English colony is found there. Pop., 1906, 51,201, 1911, 53,128. *Gesoriacum* was a fortress of the Gallic tribe of the Morini. In the time of Constantine the place was called Bononia. Under the Carolingians the name was changed to Bolonia. After the death of Charlemagne the Normans sacked it, it was taken by the Burgundians in 1435 and held until Louis XI added it to the French Kingdom in 1477. It was besieged by Henry VII of England in 1492, taken by Henry VIII in 1544, but restored to France by Edward VI in 1550. On Aug. 6, 1840, Louis Napoleon attempted here an insurrection. He was imprisoned in the castle. Consult Vivenot, *Notice sur la Port de Boulogne* (Paris, 1904), and Meridian, *Guide to Boulogne* (London, 1908).

BOULOGNE-SUR-SEINE, bōl'ōn'y'-sur-sân' (Fr. Boulogne on the Seine) A town of France, in the department of Seine, about 5 miles west of Paris, opposite Saint-Cloud, on the river Seine, which is crossed at this point by a fine stone bridge. It gives its name to the Bois de Boulogne, the great park and promenade of Paris (See PARIS). It has extensive linen bleacheries and perfume manufactories. Pop., 1906, 49,969, 1911, 57,027. The ancient name of Boulogne was *Menus-les-Saint-Cloud*, its present name being due to the church which was erected in the fourteenth century, in honor of

Notre Dame de Boulogne sur Mer. The church was restored in 1863.

BOULTON, hō'ton, CHARLES ARKOLL (1841-99). A Canadian soldier and legislator. He was born at Colburg, Ontario, and served in the British army from 1858 to 1868. During both of the insurrections in Manitoba, led by Louis Riel, he took an active part in the struggle against the rebels, was imprisoned and sentenced to death by them in 1870, and at the outbreak of the second rebellion, in 1885, organized and commanded a corps of mounted riflemen known as Boulton's Scouts. He was called to the Senate of the Dominion Parliament in 1889, and sided with the Liberal party in that chamber. He is the author of an interesting book, *Reminiscences of the North West Rebellion* (1886).

BOULTON, MATTHEW (1728-1809). An English manufacturer and engineer, born in Birmingham, where his father was a silver stamper and maker of all kinds of metal articles. At his father's death, in 1759, the younger Boulton continued the business, moving it in 1763 to Soho, near Birmingham. The growth of this factory and the consequent increased need of a stronger motive power than could be obtained from water led Boulton to direct his thoughts to the steam engine, which was then used only for pumping. He made experiments and constructed a model of an improved steam engine, but it was not a success. About 1767 he made the acquaintance of James Watt, who was working with Dr. John Roebuck to perfect a model engine, and offered him the use of his works at Soho for experimental purposes. In 1772 Roebuck failed, and Boulton, to whom he owed a large amount of money, took over his share in the engine patent as payment of the debt and became Watt's partner. He devoted to the enterprise all the money he could raise and was on the verge of bankruptcy before it was a commercial success. About 1787 he began to receive profit from the engine, and from that time the factory grew rapidly in size, and the capital invested in it was greatly increased. In his later life Boulton turned his attention to reform of the copper coinage, and in 1788 established at Soho a plant at which he struck coins for the Sierra Leone and East India companies and for Russia and in 1797 produced a new copper coinage for Great Britain. For his biography, consult S. Smiles, *Lives of Boulton and Watt* (London, 1865), and Thurston, *History and Growth of the Steam Engine* (New York, 1878).

BOU MAZA, bōō mā'zā, Sī MOHAMMED BEN ABDALLAH (1820-). An Arab leader of Algeria, who, as a dervish, in 1846, excited the people of Dahra against the French, and, with the support probably of Abd-el-Kader (q.v.), engaged in several conflicts. St. Arnaud made him a prisoner (1847) and sent him to Paris, where he received a pension and was provided with a home. He escaped in 1848, but was caught and sent as a prisoner to Ham, where he was kept a year and a half. He subsequently entered the Turkish army and fought in the Crimean War.

BOUNCING BET. See SOAPWORT.

BOUND, or **BOUNDARY** (OF. *bonne, bonde, bodne*, from I.L. *bodina, bodena*, bound, limit). The limiting lines of a parcel of land by which it may be known and described; being in this sense synonymous with *abuttals*, which means the "buttings" or boundings of land east, west,

north, and south. A boundary line marked by a fence, or by monuments, such as bounding stones, specified ties or the like, is usually conclusively taken to be the true boundary of land. An adjoining parcel of land, stream, or road, named in a deed as a boundary of the land conveyed, is a monument and as such fixes the boundary of the land described in preference to the courses and distances given in the description. See **MONUMENT**; **REAL PROPERTY**, and the authorities there referred to.

BOUND, or **BOUNDE**, NICHOLAS. See BOWDNE.

BOUND BAILIFF. In England, a deputy sheriff or sheriff's officer, whose duty is to discover and arrest debtors. As the sheriff is responsible for the misconduct of these bailiffs, they are annually bound in an obligation, with sureties, for the due execution of their office, whence the name *bound bailiffs*, which Blackstone is at pains to inform us "the common people have corrupted into a much more homely appellation," *bum-bailiff*. See **BAILIFF**.

BOUND BROOK. A borough in Somerset Co., N. J., 30 miles west-southwest of New York, on the Raritan River, the Delaware and Raritan Canal, and the Baltimore and Ohio, the Central of New Jersey, the Lehigh Valley, and the Philadelphia and Reading railroads (Map: New Jersey, C 2). It has manufactures of moving-picture films, stove polish, woolen goods, engines, electric dynamos, asbestos products, roofing paper and paint, graphite journal bearings, and lumber. The borough contains a public library. Settled about 1700, Bound Brook was first incorporated in 1892, the date of the charter now in operation, which provides for a mayor, elected biennially, and a city council. On April 13, 1777, 4000 English and Hessians under Lord Cornwallis and Count Donop surprised here about 1000 Americans under General Lincoln, who after a short resistance retreated, having lost 60 men in killed, wounded, and prisoners. Pop., 1900, 2622; 1910, 3970.

BOUNDING CHARTER. In Scots' law, an instrument of title which describes the lands thereby conveyed by their boundaries or limits. This is in all countries the oldest, as it is the preferred, method of describing land for the purposes of conveyance, being at the same time more accurate and more certain than a surveyor's description by courses and distances. In American and English law, instruments for the conveyance of land are called "deeds," and generally contain a description of the land conveyed according to its metes and *bounds*. See **CONVEYANCING**; **BOUND**; **MONUMENT**.

BOUNTY (Fr. *bonté*, goodness, from Lat. *bonitas*, goodness, excellence, from *bonus*, good). A term applied to any sum granted by law as an inducement to some undertaking believed to be of public importance. 1. Payments of bounties are sometimes made for the encouragement of commercial or industrial enterprises. The most important recent example of industrial bounties in the United States was the sugar bounty of two cents a pound under the tariff law of 1890. It is a question not yet determined, whether industrial bounties can be upheld under our Federal and State constitutions. In many instances they have been held by the courts to be in violation of the principle that money raised by taxation may be appropriated only for a public purpose.

The term "bounty" is also frequently applied to indirect pecuniary benefits arising out of the operation of fiscal laws, such as excessive drawbacks on exports or rebates on transportation charges on government railways. The so called sugar bounties of Germany and other European countries consisted nominally in an abatement of internal taxes upon exported sugar. But as the abatement was so measured that it was greater than the original tax, it constituted in fact, if not in name, a bounty upon exportation. For a discussion of the theory of industrial bounties, see FREE TRADE, SUBSIDIES.

2 Monetary inducements to encourage men to join the army or extend their service are common. Usually bounty is given only in those countries whose armies are recruited by voluntary enlistment. The amount given varies with the need and difficulty of procuring recruits. During the Civil War in the United States, as much as \$1000 was sometimes offered for enlistment. This was, however, owing to the magnitude of the war and the immense number of men required. The English government gives a bounty to men already serving in India to induce them to extend their service.

3 In the United States navy money is awarded a ship which sinks or destroys an enemy's ship of war. When the vessel destroyed is of equal or superior force, the victors are awarded \$200 for each person on board the enemy's ships at the beginning of the engagement, if of inferior force, \$100 for each person. If the ship is destroyed after the capture, for public interest, \$50 is awarded for each person on board the ship at the time of capture. The amount awarded is divided among the officers and crew in the same manner as prize money. When the number of persons on board the destroyed ship cannot be accurately ascertained, an estimate is made, based on the complement of a ship of the same class in the United States navy. This bounty is authorized by the United States laws, but Congress must first make an appropriation for that purpose.

BOUNTY, THE The name of an English vessel under the command of Captain Bligh, the crew of which in 1789 mutinied near the Friendly Islands and abandoned 19 men, including the captain, in a small boat with scant provisions. After many hardships the boat at last reached Timor, whence Bligh returned to England. In 1814, by the accidental discovery of a settlement on Pitcairn Island (q.v.), it was found that eight of the mutineers of the *Bounty* had escaped to the island and colonized it. The last of the mutineers died in 1829. The incident was used by Lord Byron in his poem "The Island."

BOUNTY JUMPER. In American history, one of the class of men who, while bounties were being paid for enlistments during the Civil War, entered the service with the intention of deserting soon after obtaining the promised reward. They would frequently reenlist under different names, and repeat the process until caught, one man, in 1865, confessing that he had "jumped the bounty" 32 times. The bounties differed in amount at different times and places. Consult Fry, *Report of the Provost Marshal General* (Washington, 1866), and Wilkinson, *Recollections of a Private Soldier* (New York, 1887).

BOUQUET, bōō'kă', HENRY (1719-65) A British soldier, who served for many years in America. He was born in Rolle, Switzerland,

entered the army of the Low Countries in 1736, served alternately with the Dutch and the Sardinians, and in 1756 entered the English service in America as lieutenant colonel of the "Royal American Regiment." He was second in command of the army which, under General Forbes, captured Fort Duquesne in 1758 (see PITTSBURGH), and was left in command when Forbes returned to Philadelphia. In 1763, while in command at Philadelphia, he was sent with 500 men to relieve Fort Pitt (formerly Fort Duquesne), then closely besieged by Pontiac's followers, and at Bushy Run, about 20 miles from the fort, defeated the Indians (August 5-6) and thereby virtually suppressed the great conspiracy (See PONTIAC). In October, 1764, he forced the Ohio Indians to make peace at Tuscarawas. He was raised to the rank of brigadier general and in 1765 was placed in command of the Southern Department of America with headquarters at Pensacola, where soon afterward he died of the fever. For the best account of his military services, consult Parkman, *Conspiracy of Pontiac* (Boston, 1867). Consult also an article on the subject in the *Pennsylvania Magazine of History and Biography*, vol. III (Philadelphia).

BOUQUET DE LA GRYE, bōō'kă' de la grē', JEAN JACQUES ANATOLE (1827-1909) A French hydrographer and astronomer. He was born in Thiers (Puy-de-Dôme) and was educated at the Ecole Polytechnique. One of his most important and difficult surveys was that of New Caledonia, of which region he prepared 40 charts (1853). He was the promoter of the project to make Paris a seaport by means of a ship canal and the widening of the Seme. Bouquet de la Grye was almost equally famous as an astronomer and as a perfecter of astronomical instruments. His works include *Pilote des côtes ouest de France* (2 vols.), *Notes sur le sondage a la mer*, *Etude hydrographique sur la baie de La Rochelle, Paris, Port de Mer* (1892), *Notes sur les sondes faites par de grandes profondeurs; Passage de Vénus, mission du Mencku* (1905).

BOUQUET (bōō'kă') OF WINE (Fr. *bouquet*, nōsegay, bunch of flowers, OF *bosquet*, dimin. from LL *boscos*, thicket). A flavor or aroma characteristic of the better class of wines and due chiefly to the presence of volatile constituents, as alcohols and esters. According to some authorities, the characteristic bouquets of wines are caused by the different kinds of yeast used in the various districts, the same must, fermented with yeasts from several different districts, has yielded wines possessing different bouquets. On the other hand, the bouquet of the wine from Riesling grapes is said to be caused by the action of frost.

BOUQUETIN, bōō'k-tăn' (Fr. for OF *bouc d'estain* *bouc*, goat + *de*, of + *estain*, bounded wool). A wild goat, stambouk, or ibex, especially that of the Alps or Pyrenees. See IBEX.

BOURASSA, HENRI (1868-). A Canadian journalist and political leader. He was born at Montreal and was privately educated. In 1886 he went to Montebello, of which he became mayor in 1890, and afterward to Papineauville, where also he was mayor in 1897, later removing to Montreal. While at Montebello he became editor of *L'Interprète*, and after 1897 his journalistic activity was continued in Montreal as contributor to *Le Nationaliste* and afterward as editor of *Le Devoir*, an independent newspaper. He entered Dominion politics

in 1896 as an Independent Liberal member of the House of Commons. He soon advocated Nationalist views, based on the conviction that French-Canadians hold under confederation a distinctive position not to be endangered by complications into which British rule might lead them. In 1899 Bourassa resigned his seat as a protest against French-Canadian support of Britain in the South African War (q.v.). In 1900 he was reelected by acclamation and afterward became known as the Nationalist leader. After the general election of 1908 he was elected to the Quebec provincial assembly. In 1911 he opposed the Liberal policy of reciprocity with the United States as prejudicial to the Nationalist position. He published several pamphlets expounding and defending his political opinions.

BOURBAKI, bōor'ba'kē', CHARLES DENIS SAUTER (1816-97). A French general. He was born at Pau, was educated at Saint-Cyr, served for some time in Algeria, and rose to the rank of brigadier general in 1854. In the Crimean War he won distinction at the Alma, at Inkerman, and in the assault on Sebastopol. He also participated in the Italian campaign of 1859. In 1869 he was commander of the second camp at Châlons and aid-de-camp to the Emperor. In the war with Germany he was placed in command of the Imperial Guard and took an important part in the conflicts around Metz. After having been for a short time at the head of the Army of the North, he was in December, 1870, placed in command of the Army of the Centre, soon transformed into that of the East. The advance of Bourbaki forced Van Werder to evacuate Dijon on December 27, but his attack upon Von Werder's position at Héricourt before Belfort (Jan. 15-17, 1871) was repulsed. He was compelled to retreat, but, finding his way towards Lyons cut off by the German Army of the South, was driven to despair and attempted suicide. General Clinchant assumed command of the army, which on February 1 sought refuge by crossing the frontier into Switzerland. Bourbaki returned to France, and became corps commander at Lyons in July, 1871. He retired in 1881. Consult, Grandin, *Le général Bourbaki* (Paris, 1897).

BOURBON, bōor'bon, *Fr. pron.* bōor'bôn', HOUSE OF. A younger branch of the Capetian family of France, representatives of which occupied several European thrones after the sixteenth century. The house derived its name from the castle and seignior of Bourbon, in the former province of Bourbonnais, in the centre of France, where now stands the little town and watering place of Bourbon-l'Archambault. The first lord or *sire* of this family of whom history makes mention was Adhémar, at the beginning of the tenth century. The fourth in succession from him, Archambault I, added the name of the family castle to his own. Under his successors, who also bore the name of Archambault, the family possessions were soon very much increased. At length the seignior of Bourbon devolved upon an heiress, who in 1272 married Robert, the sixth son of Louis IX of France. It thus passed to a branch of the royal family of the Capetians, under whom it was converted into a duchy. The principal branch of this family was, in 1523, deprived of all its dignities and possessions, because the Duke, Charles de Bourbon (q.v.), the famous Constable, allied himself with Charles V against

Francis I of France. Of the collateral branches, that of Vendôme acquired great importance, first attaining by marriage, in the person of Antoine de Bourbon, Duke of Vendôme, the throne of Navarre; afterward by inheritance the throne of France, in the person of Henry IV, on the extinction of the male line of the house of Valois (q.v.); and by fortune of war the thrones of Spain, Naples, and Parma. Among the numerous other collateral branches may be mentioned those of Montpensier, De la Marche, Condé, Conti, Soissons, and Orleans. Only a few members of the collateral lines, however, have borne the name of Bourbon; for example, the Cardinal Charles de Bourbon, Duke of Vendôme, who, under the name of Charles X, was set up by the Catholic League as a rival King to Henry IV. The dual dignity was revived by Louis XIV in the house of Condé (q.v.), so that the eldest son of that house should bear the title of Duke of Bourbon.

The dynasty of the Bourbons in France begins with Henry IV (q.v.), who, after the assassination of Henry III, became, by virtue of the Salic law (q.v.), the heir to the French throne. Through his father, Antoine de Bourbon, King of Navarre and Duke of Vendôme, he was descended from Robert, son of Louis IX, and husband of Beatrix, heiress of Bourbon. On his assassination in 1610, he left, by his second wife, Maria de' Medici, five legitimate children: (1) Louis XIII, his successor on the throne; (2) Gaston, Duke of Orleans (q.v.), who died in 1660, and left no male heirs; (3) Elizabeth, married to Philip IV of Spain; (4) Christina, married to Victor Amadeus, afterward Duke of Savoy; (5) Henrietta, married to Charles I of England.—Louis XIII, on his death in 1643, left two sons by his Queen, Anne of Austria, daughter of Philip III of Spain: (1) Louis XIV, his successor; and (2) Philip, who received from his elder brother the title of Duke of Orleans and was the founder of the family which has become the younger Bourbon dynasty.—The Dauphin Louis, son of Louis XIV by his marriage with Maria Theresa of Spain, died in 1711 and left three sons by his marriage with Maria Anna of Bavaria: (1) Louis, Duke of Burgundy; (2) Philip, Duke of Anjou, who afterward became King of Spain, as Philip V; (3) Charles, Duke of Berry, who died in 1714.—Louis, Duke of Burgundy, died in 1712. By his wife, Maria Adelaide of Savoy, he had three sons, of whom two died in early youth, the only one who survived being Louis XV, who succeeded his great-grandfather, Louis XIV, in 1715.—Louis XV having married Maria Leszcynska, daughter of the dethroned King Stanislas of Poland, had by her a son, the Dauphin Louis, who married Maria Josepha of Saxony and died in 1765, leaving three sons: (1) Louis XVI, who succeeded his grandfather, Louis XV, in 1774; (2) Louis Stanislas Xavier, Count of Provence, afterward Louis XVIII; (3) Charles Philippe, Count of Artois, afterward Charles X.—Louis XVI had three children by his Queen, Marie Antoinette of Austria: (1) The Dauphin Louis, who died in 1789; (2) Louis, called Louis XVII, who died in 1795; (3) Marie Thérèse Charlotte, styled Madame Royale, afterward Duchess of Angoulême.—Louis XVIII had no children; but Charles X had two sons: (1) Louise Antoine de Bourbon, Duke of Angoulême who was Dauphin prior to the Revolution of 1830 and died without issue in

1844, (2) Charles Ferdinand, Duke of Berry (q.v.), who was murdered in 1820—The Duke of Berry left two children (1) Marie Louise Thérèse, styled Mademoiselle d'Artois, married to the Duke of Parma, (2) Henri Charles Ferdinand Marie Dieudonné, Duke of Bordeaux, later styled Count of Chambord, the representative of the elder branch of the Bourbons. The latter died childless in 1883, and the Legitimists accepted in his stead the Orleanist Count of Paris, grandson of King Louis Philippe, as head of the house of Bourbon. The Count of Paris died in 1894, and his son, the Duke of Orleans, now represents legitimacy.

The founder of the Orleans or younger branch of the Bourbon royal family of France was Philip, Duke of Orleans, the younger brother of Louis XIV. He died in 1701, leaving, by his second marriage, with Elizabeth Charlotte of the Palatinate, a son of his own name as his heir, who was regent of France during the minority of Louis XV. The latter's son, Louis Philippe, Duke of Orleans (born 1703), married a princess of Baden, and died in 1752, leaving an only son of his own name (1752-85), whose son and heir was that Louis Joseph Philippe, Duke of Orleans, so notable in the French Revolution, who in 1792 renounced his rank, taking the name of Citizen Egalité, and died by the guillotine in 1793—PHILIPPE EGALITÉ left four children (1) Louis Philippe, who before the Revolution was styled Duke of Chartres—that being the ordinary title of the eldest son of the Orleans family—became afterward Duke of Orleans, was King of the French from 1830 to 1848, and died in England on Aug. 26, 1850, (2) the Duke of Montpensier, who died in England in 1807, (3) the Count of Beaujolais, who died at Malta in 1808, (4) Adelaide, styled Mademoiselle d'Orléans (1777-1847)—Louis PHILIPPE left a numerous family by his Queen, Amelia of Naples. His eldest son, Ferdinand, Duke of Orleans, lost his life in an accident on July 13, 1842, leaving by his wife, the Princess Helen of Mecklenburg-Schwerin, two sons, the eldest of whom, Louis Philippe Albert, Count of Paris (1838-94) (q.v.), left as his heir Louis Philippe Robert, Duke of Orleans, born Feb. 6, 1869. Concerning the other members of Louis Philippe's family, see LOUIS PHILIPPE.

Louis XIV having succeeded in placing his grandson, Philip, Duke of Anjou, on the throne of Spain, in 1700, as Philip V, this prince became the founder of the Spanish Bourbon dynasty, as well as of the Bourbon dynasties of Naples and Parma and Piacenza. These dynasties endured only a temporary overthrow from the policy and aims of Napoleon Bonaparte. Philip V was succeeded on the Spanish throne by his son, Ferdinand VI, who died without issue in 1759, and the crown fell to his brother, Charles III, whose son and successor, Charles IV, was compelled to resign it in 1808, in favor of a successor nominated by Napoleon, and died at Naples in 1819. The two eldest sons of Charles IV by his marriage with Maria Louisa of Parma were (1) Don Fernando, Prince of Asturias, who after the overthrow of Napoleon reigned as Ferdinand VII, whose eldest daughter was Isabella II, the mother of Alfonso XII, (2) Don Carlos (see CARLOS DE BOURBON), who in 1833 became pretender to the Spanish throne and in 1845 resigned his pretensions in favor of his son, Don Carlos, who styled himself Count of Montemolin. He died at Trieste, 1855, leaving

his claim to the Spanish throne to his nephew Don Carlos, who in turn, upon his death in 1909, left it to his son Prince Jaime. The Count of Montemolin died in 1861, and his claims to the Spanish throne are now represented by his nephew, Don Carlos, son of his brother Juan.

When the Bourbon dynasty was established on the throne of Spain in the person of Philip V, Naples and Sicily were severed from that monarchy (1713-14). Naples was given to Austria, and Sicily to Savoy, which in 1720 ceded the island to Austria in exchange for Sardinia. In the Treaty of Vienna (1735), Don Carlos, son of Philip V, became King of the Two Sicilies, as Charles III. Upon his accession to the throne of Spain in 1759, he gave up that of the Two Sicilies to his third son, Don Fernando, called Ferdinand IV, with the express stipulation that it should never again be occupied by a King of Spain. Ferdinand IV was deprived of Naples by Napoleon in 1806, but after the overthrow of Napoleon he recovered it, and in 1816 he proclaimed himself King of the consolidated realm of the Two Sicilies as Ferdinand I. His son, Francis I, left the throne in 1830 to his son Ferdinand II (q.v.), whose son, Francis II, was expelled in 1860, when Naples was incorporated with the new Kingdom of Italy.

By the Peace of Aix-la-Chapelle in 1748, Austria made over the duchies of Parma and Piacenza to Don Philip, the youngest son of Philip V of Spain, but with the stipulation of their reversion to Austria on the failure of male descendants, or on his succeeding to the throne of Spain. He was succeeded in 1765 by his son, Ferdinand I, whose son, the hereditary Prince Charles Louis, was made King of Etruria in 1801 under the guardianship of his mother, Maria Louisa of Spain, the cession of Parma and Piacenza to France on the death of Ferdinand being provided for. Ferdinand died in 1802, and in 1807 Napoleon took possession of Etruria. The Congress of Vienna assigned Parma and Piacenza for life to Maria Louisa of Austria, the spouse of Napoleon, but meanwhile indemnified Maria Louisa of Spain with the Duchy of Lucca. The latter was succeeded in 1824 by her son Charles Louis. He made over Lucca to Tuscany in 1847, and in the same year Parma and Piacenza reverted to the Bourbon family, in his person. He abdicated on March 14, 1849, and was succeeded by his son, Charles III, and he in 1854 by his son Robert—born 1848—whose mother, Marie Louise Thérèse de Bourbon, daughter of the Duke of Berry, then became regent of the duchies. The Bourbons, however, were permanently deprived of these states as well as of Naples and Sicily by the incorporation of the two duchies in the Kingdom of Italy in 1860. See ITALY and PARMA.

BOURBON, bōōr'bōn', ANTOINE DE. See ANTOINE DE BOURBON.

BOURBON, CHARLES, DUKE OF (1489-1527). A French general, known as the Constable de Bourbon. He was the son of the Count of Montpensier. In consequence of the death of his elder brother, and his marriage with the only daughter of the Duke of Bourbon, he united in his own possession the vast estates of both these branches of the Bourbon family, which alone at that time retained the old feudal power. He distinguished himself by the brilliancy of his exploits in arms and by his rigid morals. Promoted at an early age to the highest military position in France, that of constable, he proved his ability by leading in 1515 the forces of Francis I across the Alps by passes hitherto deemed unpracticable. His valor contributed greatly to the victory of Francis at Marignano (Sept. 13, 14, 1515), and he followed up this success by the capture of Milan a few days later. Accounts differ as to his later career. It is charged by French historians that Charles of Bourbon was the victim of an overweening pride and jealousy, that he claimed more credit than really belonged to him, and that his treason was not at all justifiable. On the other hand, he is represented as the victim of a woman's revenge. It is said that Marie Louise, the King's mother, became enamored of the brave constable; and that he, although a widower, declined her hand, openly declaring that he deemed her a woman devoid of modesty and not to be thought of for a wife. Through her influence the estates which he had acquired through his wife were seized and his perquisites as constable were withheld. Thus deeply injured, he renounced the interest of France and concluded a private alliance with the Emperor Charles V and with Henry VIII of England for the conquest and partition of France. The King, who was engaged in an expedition to Italy, received intelligence of this conspiracy. He proceeded forthwith in person to the constable and offered him restoration to favor and also to his estates. The constable, however, did not trust him, but fled in disguise, and reached Franche-Comté in 1523. He attacked, in 1524, the French army on its march over the Alps and planned with the Spaniards an invasion of France. But Charles V did not entirely trust him and appointed the Marquis of Pescara to assist and watch him. He was forced to relinquish the siege of Marseilles on the approach of Francis I with a great army. He repossessed the Alps and took his revenge in the battle of Pavia, Feb. 24, 1525, where the King was made a prisoner. (See FRANCIS I.) He now went to Madrid, but soon found himself disappointed in his hopes and returned to Lombardy to carve out his own fortune. He took Milan from Maximilian Sforza and then assailed Rome. In the assault, May 6, 1527, he was mortally wounded by a bullet, which Benvenuto Cellini afterward asserted that he had shot. His death was kept secret for a time from the army under his command. The city was sacked, and when the army departed from Rome two months later, his corpse, which the soldiers would not part with, was taken with them and buried at Gaeta, under a magnificent monument, which, however, was afterward destroyed. (See BOURBON, HOUSE OF, for

genealogy and references.) Consult: Coignet, *Francis the First and his Times* (London, 1888); Robertson, *History of the Reign of Charles V* (Philadelphia, 1864-67); Lavisse, *Histoire de France*, vol. v (Paris); Hare, *Charles de Bourbon, High Constable of France* (London, 1910).

BOURBON, ÎLE DE. See RÉUNION, ÎLE DE LA.

BOURBON, LOUIS DE. See SOISSONS, COUNT OF.

BOURBON, LOUIS ANTOINE HENRI DE. See ENGHEN, DUC D'.

BOURBON, LUIS MARIA DE (1777-1823). A Spanish prelate and politician. He was born at Cadahalso, took orders, was appointed Archbishop of Seville in 1799, Archbishop of Toledo in 1800, and in the latter year received also the cardinal's hat. During the French occupation he was president of the Cadiz regency, and as such approved the decrees of the Constituent Assembly of the Cortes. Thus he signed the constitution of 1812 and abolished the Inquisition. The refusal of the King, on his return in 1814, to accept the constitution precipitated a revolution. Bourbon's activity gained for him the post of president of the provisional government junta then organized, and the King was forced in 1820 to give up part of his power.

BOURBON-LANCY, bōōr'bōn' lān'sē'. A watering place in the department of Saône-et-Loire, France, 40 miles northwest of Charolles (Map: France, N., J 6). It is celebrated for its thermal springs, which contain chloride of sodium and iron. The town has a hospital with 400 beds built by the Marquis d'Aligre. Pop., 1901, 4158; 1911, 4469. The Romans knew this city as Aquæ Nisinei or Nisienses, and remains of their baths are to be seen. It was a stronghold of the Bourbon family in the Middle Ages.

BOURBONNAIS, bōōr'bōnā' (so called from *Bourbon*). A former province of central France, now comprised within the departments of Allier, Cher, and Nièvre. From 1327 to 1523 it formed the Duchy of Bourbon. In the latter year it was annexed to the crown, but was bestowed, in 1661, on the house of Bourbon-Condé, which held it until the Revolution. Consult: Nicolay, *Description et histoire du Bourbonnais* (Moulins, 1875); Mauve, *Le Bourbonnais sous la Seconde République* (London, 1909).

BOURBONNAIS. A village in Kankakee Co., Ill., 56 miles south of Chicago (Map: Illinois, E 2). It is the seat of Notre Dame Convent and of St. Viator's College (Roman Catholic), opened in 1865. Pop., 1900, 595; 1910, 611.

BOURBONNE-LES-BAINS, bōōr'būn' la bān' (Fr. The Baths of Bourbonne, *Ml. Bourbonia*, in Roman times *Aqua Borvonia*, Baths of Borvo, Borvo being among the Gauls a name for Apollo). A town and watering place in the department of Haute-Marne, France, pleasantly situated by the Amana on an eminence amid wooded country, 20 miles east-northeast of Langres (Map: France, N., L 5). Saw mills and the manufacture of plaster are the chief industries. It has a fine church of the twelfth century, a large military hospital, and some interesting ruins of a château of the ancient Seigneurs de Bourbonne. Its thermal springs attract some 3000 invalids annually. They are strongly impregnated with chloride of sodium, and their temperature is from 140° to 150° F. Pop., 1901, 4014; 1911, 3707.

BOURBOULE, bōōr'bōul', LA. A health resort in the department of Puy-de-Dôme, France, on the Dordogne, 22 miles southwest of Clermont. It is noted for its mineral thermal

springs and is visited annually by over 7000 persons, while its bottled waters constitute a thriving export industry Pop, 1901, 1404, 1911, 1314

BOURCHIER, bōŕ'chî-ër, *Fr* pron bōŕ'-shyâ', ARTHUR (1864-) An English actor and manager. He was born at Speen, Berkshire, and educated at Eton and Oxford. While at the university he won distinction as an amateur actor, and in 1889 he went upon the professional stage, playing with Mrs Langtry, at Wolverhampton, as Jacques in *As You Like It*, in which he appeared in London the next year at the St James's Theatre. Later he played for a time at the Criterion. In March, 1892, he was at the Shaftesbury Theatre, in his own play of *Mr Richards*. Soon afterward he joined Augustin Daly's company and went to America, returning early in 1893 to play at Daly's London theatre, where he had the rôle of Robin Hood in Tennyson's *Foresters*. In 1894 he married Miss Violet Vanbrugh, a talented actress, who has continued upon the stage with her husband. In the fall of 1895 he took the Royalty Theatre, producing among the plays *The Ohls Widow*, an adaptation of his own, which ran for over 300 nights. Subsequently he appeared in leading parts at the Garrick, Strand, and Court theatres and, with Charles Wyndham, at Wyndham's Theatre. Then, as Wyndham's partner at the Criterion, he helped to bring out *His Excellency the Governor* and *Lady Huntworth's Experiment*. In September, 1900, he entered into the management of the Garrick Theatre, where he produced many of the best-known contemporary plays. In 1910 he joined Sir Herbert Tree at His Majesty's Theatre and made a notable success in the rôle of King Henry VIII and continued to appear there in Shakespearean repertoire during 1911.

BOURDALOUE, bōŕ'da'loo', LOUIS (1632-1704) One of the greatest preachers of France. He was born at Bourges, Aug. 20, 1632, and after having, at the age of 16, entered the order of Jesuits, obtained in succession the chairs of humanity, rhetoric, philosophy, and theological ethics in the academy of his native place. He showed a great capacity for science, but his remarkable powers of eloquence led his superiors finally to determine upon employing him as a preacher. Disdaining the inflated style prevalent among the tasteless pulpit orators of his time, he assailed with manly vigor and truly religious earnestness the passions, weaknesses, and errors of men. The dignity of his manner and the fire of his eloquence made him famous even when the public mind was occupied with the festivities of Versailles, the victories of Turenne, and the literary masterpieces of Corneille and Racine. At the court of Louis XIV he was remarkably well received. After the revocation of the Edict of Nantes (1685) he was sent to Montpellier to convert the Protestants. Bourdaloue particularly understood how to accommodate his eloquence to the minds of those whom he addressed. Simple among the simple, a dialectician among ecclesiastics, he was equally a favorite with the common people and with the learned and the great. He was also much esteemed and beloved as a man and in all circumstances maintained unimpeached a high reputation for candor and honesty. In the later years of his life he relinquished the pulpit and devoted his time to hospitals, prisons, and pious institutions. He died in Paris,

May 13, 1704. How thoroughly his religious sentiments were governed by the theological tenets of his Church may be perceived from these remarkable words which he uttered on his deathbed: "It is highly reasonable that God be fully satisfied, and at least in purgatory I will suffer with patience and with love." His *Sermons and Moral Discourses* appeared in English translation (3d ed., Dublin, 1855), also his *Married Life Its Obligations, Trials, etc.* (London, 1897), several French editions of his works have been published, e.g., *Collection universelle des orateurs sacrés*, vols. xiv-xvi, reprint of François Bretonneau's edition (6 vols., Paris, 1891). For his biography, consult Anatole Feugère, *Bourdaloue, sa prédication et son temps* (Paris, 1874, 5th ed., 1889), M. Lousas (2 vols., Paris, 1881), and L. Pouthe (Paris, 1900), also J. B. E. Tousserat, *Etude généalogique sur les Bourdaloue* (Paris, 1900), Brooke, *Great French Preachers* (London, 1904).

BOURDELLES, bōŕ'dâ'y' See BRANTÔME. **BOURDON**, bōŕ'don' (*Fr*, *It* *bordone*, a humming, a buzzing; a drone, *ML* *burdo*, drone, cf *Eng* *burden*, refrain of a song) In music, a drone bass produced by a bagpipe or hurdy-gurdy, also an organ stop, consisting of stopped wooden pipes, usually of 16-feet tone.

BOURDON, bōŕ'don', SÉBASTIEN (1616-71). A French painter, born in Montpellier. He studied in Paris under a mediocre artist named Barthélemy, and from 1634 to 1636 in Rome, where he was much influenced by his countrymen Nicholas Poussin and Claude Lorraine. After his return to Paris he firmly established his reputation by his "Martirdom of St Peter" (Louvre Gallery) and became one of the 10 original members of the Academy of Painting. In 1652-54 he was in Sweden as court painter to Queen Christina, whose portrait by him is in the National Gallery, Stockholm. He was subsequently rector of the Academy of Painting. He is known chiefly as an historical painter, but he worked also in other styles. His paintings are generally brilliant and of large grasp, but sometimes lack care in drawing and are dull in color. They further include "Descent from the Cross" (Louvre), "Julius Caesar before the Tomb of Alexander" (Louvre), "Group of Merchants" (Museum of The Hague), "Return of the Ark from Captivity" (National Gallery, London).

BOURDON DE L'OISE, bōŕ'don' de lwâz', FRANÇOIS LOUIS A notorious character of the French Revolution. He was born in the middle of the eighteenth century, at Saint-Remy, near Compiègne, and became a procurator in the Parlement of Paris. He participated in the storming of the Tuileries on Aug. 10, 1792. He shortly afterward obtained a seat in the Convention by a trick which, though subsequently discovered, did not lead to his ejection. Bourdon de l'Oise contributed much to bring about the execution of Louis XVI, the insurrection of May 31, and the destruction of the Girondists. He was sent to La Vendée, where, however, he loudly condemned the Revolutionary cruelties and assumed the attitude of a moderate. Obnoxious on this account to Robespierre and Hébert, and fearing for his head, he urged with the greatest eagerness the overthrow of the Terrorists on the 9th Thermidor (July 27), 1794. From this time forth Bourdon de l'Oise showed himself an enemy of the clubs and a protector of the nobles and the priests. In con-

sequence of the insurrection of 13th Vendémiaire (Oct. 5), 1795, he was sent as a commissioner to Chartres, where he behaved harshly and brutally. He passed from the Convention into the Council of Five Hundred, became a persecutor of the Republicans, and joined a Royalist club. The Directory placed him upon the proscribed list, after the 18th Fructidor (Sept. 4), 1797. He was transported to Cayenne (French Guiana) where in a short time he died in great misery.

BOURGAS. See BURGAS.

BOURGAULT-DUCOUDRAY, būr'gō'-dū'-kō'drā', LOUIS ALBERT (1840-1911). A French composer and writer on music, born at Nantes, Feb. 2, 1840. He began life as a lawyer, but soon abandoned that profession and entered the Conservatory at Paris, where he studied composition under A. Thomas. In 1865 he won the *Prix de Rome* with his cantata *Louise de Mémoires*. After three years of study in Italy he returned to Paris in 1868, and founded a choral society for the performance of the works of the older masters. In 1872 he went to Greece for the purpose of studying the music of the Greek church. The results of his investigations he published in the works entitled *Souvenirs d'une mission musicale en Grèce, Trente mélodies populaires de Grèce et d'Orient, and Etudes sur la musique ecclésiastique grecque*. In 1878 he was appointed professor of the history of music at the Paris Conservatoire. His compositions include a *Statut Mater*; the comic operas, *L'atelier de Prague* (1858), *Michel Colombe* (1887); the grand opera *Thamara* (1891); compositions for orchestra, *Plantasy in C minor, Carnival d'Athènes, Rhapsodie cambodienne, L'Enferment d'Ophélie*; and the choral works with orchestra, *Hymne de la joie, Prométhée, La conjuration des fleurs*.

BOURGELAT, būrzh'ā', CLAUDE (1712-79). A French lawyer, the founder of the first veterinary school in Europe. He was a learned lawyer, an able writer, and numbered among his friends such men as D'Alembert, Pembroke, Voltaire, Buffon, and Haller. He was impelled to further the cause of veterinary science by his fondness for horses. In 1761 he and a minister of Lyons, named Bertin, opened the first veterinary school in the suburbs of that city. It was patronized by students from all parts of France, Italy, Switzerland, Germany, Sweden, and Denmark. From this school all other veterinary colleges in Europe sprang, and with them it has kept pace, being superior to the majority, and rivaling the very best, even those of Paris and Berlin. His principal works are: *Elements d'hippiatrique* (3 vols., 1750-53); *Anatomie comparée du cheval, du bœuf et du mouton* (1766); *Règlement sur les écoles vétérinaires de France* (1777).

BOURG-EN-BRESSE, būr'g'ān-brēs' (Fr. fort in Bresse, an ancient province of France; anciently *Villa de Burgo in Bressia*). The chief town of the department of Ain, in France, situated on the Reyssouse, 38 miles northeast of Lyons (Map: France, S, K 2). The streets are crooked and narrow but clean, and the squares are adorned with statues and fountains. In the town are the Gothic church of Notre-Dame (1505-45), with a Renaissance portal, and the more important church of Brou (1511-36), the subject of a celebrated poem by Matthew Arnold. There are manufactories of tallow, soap, earthenware, iron goods, and mineral waters, and a trade in grain, cattle, and poultry. The church

of Brou was built by Margaret of Austria (died 1530), wife of Philibert II, Duke of Savoy, in fulfillment of a vow made by her mother-in-law, Margaret of Bourbon, and it contains the elaborate tombs of these three. Pop., 1901, 14,919; 1911, 20,545. Consult Charvet, *Les édifices de Brou à Bourg-en-Bresse* (Paris, 1897).

BOURGEOIS, būr'jōis'. See PRINTING.

BOURGEOIS, būr'zhwā', ANICET. See ANICET-BOURGEOIS.

BOURGEOIS, būr'zhwā', LÉON VICTOR AUGUSTE (1851-). A French politician. He was born in Paris and studied at the Lycée Charlemagne. In 1877 he became general secretary of the department of Marne, and in 1880 subprefect of Rheims. In 1882 he became prefect of Tarn and in 1885 of Haute-Garonne. He became director of the Ministry of the Interior in 1886, and in 1887 prefect of police. He was elected deputy for Marne in 1888, in the same year was appointed Undersecretary of State in the Ministry of the Interior, and in 1889 became Minister of the Interior. From 1890 to 1892 he was Minister of Public Instruction, and from December, 1892, to March, 1893, as Minister of Justice he vigorously prosecuted the Panama scandals. In 1895 he became Prime Minister, but having formed a Radical cabinet which the Senate refused to support, he resigned in the following year. In 1898 he became Minister of Public Instruction, but left office in the same year with the rest of the Brisson cabinet. In 1899 he was the head of the French delegation to The Hague Peace Conference, and from June, 1902, to January, 1904, presided over the Chamber of Deputies. In March, 1906, he became Minister of Foreign Affairs in the Sarrien cabinet, and in 1912 he was appointed Minister of Labor. He again headed the French representatives in the Peace Conference of 1907. He published *L'Education de la démocratie française* (1897), and *Essai d'une philosophie de la solidarité* (1897; 7th ed., 1912).

BOURGEOIS GENTILHOMME, būr'zhwā' zhān'tē'lām', LE (Fr. The Bourgeois Turned Gentleman). The title of a popular comedy by Molière (1670). Here we meet M. Jourdain, who had been "speaking prose all his life without knowing it."

BOURGEOISIE, būr'zhwā'zē'. The word is derived from the French word *bourgeois*, meaning "a citizen of a town," but it has come to refer to the social middle class as opposed both to the aristocracy and to the working class. It was the bourgeoisie of France who rose against the aristocracy in the French Revolution. Today the bourgeoisie in France and in the rest of the western world are the object of attack of the laboring classes. The adjective "bourgeois," following the social development, has, at the hands of some modern writers, come to stand for a more or less unthinking conservatism.

BOURGES, būrzh (Lat. *Bituriges*, a tribe of Gaul). The ancient capital of Berry, now of the department of the Cher, France, the seat of an archbishopric, and a military arsenal, situated in the midst of a fertile plain, at the confluence of the Annon and the Yèvre, 123 miles south of Paris (Map: France, N, H 5). High towers still mark points on the ramparts which surrounded the old town, but shady boulevards now take the place of the dismantled walls. The old town, standing in the heart of the new town, has crooked streets and quaint houses.

Its important buildings are the cathedral of St Etienne, begun in the thirteenth century, and the Palais de Justice. Bourges is a centre of trade in wine, grain, cloth, cattle, hemp, and millstones. It has iron foundries, tanneries, and cloth factories, but its prosperity depends to a great extent on government gun and powder works. Pop., 1901, 46,551, 1911 45,735. Bourges was the capital of the Gallic Bituriges, and the Roman *Avaricum*, after its capture by Julius Caesar in 52 B.C. It was successively taken by the Visigoths, under Euric, by Clovis, Pepin the Short, and the Normans. When Orleans was occupied by the English, Charles VII made it his capital. Its university, at which Calvin, Amyot, and Theodore de Beza studied, was abolished in the Revolution. It was the birthplace of the astute Louis XI, the eloquent Bourdaloue, and the famous Jacques Cœur, whose house is now the Palais de Justice. Consult Archalet, *Au pays de Jacques Cœur Bourges* (Bourges, 1900).

BOURGET, бѡржѣт, Lac no. A beautiful lake in the department of Savoie, France, 7 miles northwest of Chambéry (Map France, S, K 3). A railway which skirts its eastern shore connects Chambéry with the village of Le Bourget at the south end of the lake. The lake, inclosed by picturesque heights, is 10 miles long, 3 miles broad, and 475 feet deep, it is famed for its "lavaret," a species of fresh-water mackerel, its outlet is by the Canal de Savières on the northwest, which connects with the Rhone. The Château de Châtillon, the monastery of Hautecombe, and the ancient château of Bourdeaux are conspicuous features in the vicinity. Pop. of Le Bourget, 1901, 1309, 1911, 1340.

BOURGET, LE, or LE BOURGET-DRANCOY—A village in the French department of Seine, about 6 miles northeast of Paris (Map Paris and vicinity). In the Franco-Prussian War it was the scene of serious French repulses, especially the disasters of Oct 30 and Dec 21, 1870. Pop., 1896, 2550, 1901, 2808, 1911, 3979.

BOURGET, PAUL (1852—) A notable French analytic essayist and novelist. He was born at Amiens, Sept 2, 1852. His father was a Russian, his mother English, while he is himself a cosmopolitan by instinct, study, and travel, lacking provincial prejudices, but also national conviction—a typical scholarly dilettante. After a brilliant school career, finished at the famous Collège de Sainte-Barbe in Paris, he began life as a journalist and, as seems the French custom, made his first bow to literature in a volume of daintily hedonistic and pessimistic verse that earned him from Augier the name of "Melancholy Pig." These sighs of *Restless Life* (*La vie inquiète*, 1874), breathed in Latin Quarter cafés, were repeated in *Edel* (1878) and *Les aveux* (1882). With the *Essais de psychologie contemporaine* (1883), followed by *Nouveaux essais* (1885), and three volumes of *Études et portraits* (1888–89, 1906), Bourget appears in his own words as "a moralist of the decadence," "a maniac of psychology," and "a passionate lover of analysis." He did here as critic what he was to do later as novelist: he carried realistic observation beyond the externals of Zola and Maupassant to what he called "states of soul." Thus he unites the methods of Stendhal and of Balzac, and it is by no accident that one of the first of his essays is devoted to the former writer, whose reputation he did much to re-establish. Bourget called himself a moralist,

but he was rather an analyst, offering a brilliant diagnosis, but no prescription. His criticism reflects the dilettante skepticism of Renan, and his early fiction bears strong marks of the same influence, which even the later novels do not wholly avoid. They have been happily described as a seductive if somewhat sickly product of the hothouse of an outworn civilization, uniting intellectual keenness with morbid sensitiveness, dealing by preference with the cosmopolitan types of that low life which is usually called "high." In the early novels there is a good deal of snobbishness which he himself mocks in the later ones. *Mensonges* (1887) marks the cardinal point of his fiction. *L'Irréparable* (1884), *Cruelle énigme* (1885), *Crime d'amour* (1886), *André Cornélius* (1887), place the interest in situation and environment rather than in character. Analysis is attempted, but description predominates. In the later fiction, *Le disciple* (1889), *Terre promise* (1892), *Cosmopolis* (1892), *Un scrupule* (1893), *Steeplechase* and *Un saint* (1894), *Idylle tragique* (1896), *Les complications sentimentales* (1898), *La duchesse bleue* (1898), *Voyageuses* (translated as *Antigoné*), *Drame de famille* (1900), *Un homme d'affaires* (1900), *Le fantôme* (1901), as well as in the cynical *Psychologie de l'amour moderne* (1890), and in the impressions of travel, *Sensations d'Italie* (1891), *Nouveaux pastels* (1891), *Outre-Mer*, composed after a visit to the United States (1895), the dominant interest is in a morbid psychopathology and significantly peculiar "states of soul," though the latest volumes of fiction show increasing subtlety, maturity, and moral strength. Before *Cosmopolis* (1892) the ethical triumph is with cynical selfishness, though common-sense moralists like the Abbe in *Mensonges* occasionally find a tongue to describe their fellow-actors, justly enough, as "wretches who live at the mercy of their sensations." From *Cosmopolis* onward, Bourget swims with the wave of reaction towards religious sentiment and curiosity that came from a union of the spiritual mysticism of the Russians with the sensuous mysticism of Baudelaire and has affected the work of many others. This tendency is especially prominent in *L'Étape* (1902), with which, according to Brandes, "he enters into the ranks of Catholic souaves," and *Un divorce* (1904). *Monique* (1902) and *L'Eau profonde* (1903) are collections of tales. Bourget's style is very uneven, affected, incorrect at times, but capable of a terse simplicity that unites strength and beauty to a rare degree. In temper the impression that he leaves is of a passive disillusion. Nearly all of Bourget's work since 1892 is translated into English. He was elected to the French Academy in 1894. Among other and later works of his may be mentioned *L'Émigré* (1907), *L'Envers du décor* (1911), *La Crise* and *Pages de Critique et de Doctrine* (1912), and the *Complete Works*, 12 vols., up to 1913. Consult Renard, *Les préfaces de la jeune critique* (Paris, 1890), Doumic, *Deuxièmes d'auteurs d'aujourd'hui* (Paris, 1894), Pellissier, *Essais de littérature contemporaine* (Paris, 1893), and Lemaître, *Les contemporains*, vol. III (Paris, 1886–89), Sargent, *Les Grands Convertis* (Paris, 1906). Recent criticism of Bourget may be found in Capus, *Le théâtre de M. Paul Bourget* (Paris, 1911), Giraud, *M. Paul Bourget* (Paris, 1911), W. Stephens, *French Novelists of To-Day* (New York, 1908), and Plat, *Figures de ce Temps* (Paris, 1913). See Cynicism.

BOURGOIN, bōōr'gwān'. The capital of a canton in the department of Isère, France, on the Bourbre, 9 miles northwest of La Tour du Pin (Map: France, S., K 3). It is the seat of active linen, woolen, paper, and other industries. Situated on the ancient marsh bed of the Rhône, it was known to the Romans as *Bergusum*. Pop., 1901, 5246, 1911, 5623.

BOURGOING, bōōr'gwān', JEAN FRANÇOIS, BARON DE (1748-1811). A French diplomat, born in Nevers. He so distinguished himself in the military school in Paris that the government sent him to the University of Strassburg to prepare himself for diplomatic service. After studying there he spent four years in Germany on different military and diplomatic missions. In 1777 he was sent to Madrid as First Secretary of Legation, and during his seven years' residence there he wrote his best-known book, *Nouveau voyage en Espagne, ou Tableau de l'état actuel de cette monarchie* (3 vols., 1789). In 1791 he was made Minister Plenipotentiary of Louis XVI to Madrid, and subsequently took a conspicuous share in negotiating the peace preliminaries with Spain. In 1808 he became Minister to Saxony and was present in his official capacity at the Congress of Erfurt. In addition to the above-mentioned appointments he held numerous other diplomatic posts in Germany and Holland. His *Mémoires historiques et philosophiques sur Pie VI* (1798) is his most important historical work. He is also author of *Voyage du duc du Châtelet en Portugal* (2 vols., 1808).

BOURIGNON, bōōr'nyōn', ANTOINETTE (1616-80). A Flemish religious visionary, once very popular. She was born at Lille, Jan. 13, 1616. Her father was a merchant, and she inherited from him a considerable patrimony. She was so ugly an infant that there was some thought of killing her as a monstrous birth. Her intellect, however, was very acute, and its powers were early developed, along with a tendency to religious mysticism, which was much encouraged by the reading of mystic books, till her imagination became inflamed, and she began to fancy that she saw visions, conversed with God, received special revelations, and was called to restore the pure spirit of the Gospel. By the good offices of the Archbishop of Cambrai she obtained admission into a convent, where she won over some of the nuns to her opinions and soon found herself at the head of a considerable party. She afterward had charge of a hospital at Lille, but from this position she was driven in consequence of her extravagant fancies. She now traveled through various countries, her enthusiasm gaining proselytes, whose conversion, she said, caused her to suffer the pains of childbirth. At last she was appointed head of a hospital in East Friesland. According to Madame Bourignon, religion consists in internal emotion and not in either knowledge or practice. Among the chief exponents of Bourignonism was Peter Poirer, a Calvinistic minister. It spread to a remarkable extent among both Roman Catholics and Protestants; and about the end of the seventeenth century and the beginning of the eighteenth prevailed so much in Scotland that a solemn renunciation of it was demanded from every entrant on the ministry at his ordination. A minister of Aberdeen was deposed for it in 1701. The formal renunciation of Bourignonism is still continued in the Established Church of Scotland, but has been given up as needless by other Presbyterian churches. She died at

Franeke, Oct. 30, 1680. The works of Madame Bourignon were edited by Poirer (19 vols., Amsterdam, 1680-86; 2d ed., 1717). They exhibit not a little fiery eloquence. Several of her works—e.g., *Treatise of Solid Virtue* (1699), *Restoration of the Gospel Spirit* (1707)—have been translated into English, and *The Light of the World* reprinted (London, 1863) from the edition of 1696.

BOURINOT, bōōr're-nōt, SIR JOHN GEORGE (1837-1902). A Canadian historian, born in Sydney, Nova Scotia, Oct. 24, 1837. After graduating from Trinity College, Toronto, he turned to journalism, establishing the *Halifax Reporter*, which he conducted for many years. In 1880 he became clerk of the Dominion House of Commons, a post which he long held. He took an active part in the proceedings of the Royal Society of Canada (established 1882), of which he became president and later honorary secretary. Here first appeared several admirable papers in politics and history, afterward expanded into books. He also contributed to the leading periodicals on both sides of the Atlantic. Among his books are *Parliamentary Procedure and Practice* (1884; new ed., 1891); *Manual of Constitutional History* (1888); *Parliamentary Government in Canada* (1892); *How Canada is Governed* (1895); *Cape Breton and its Memorials of the French Régime* (1892); *Canada under British Rule* (1900); *Intellectual Development of the Canadian People* (1880); *Canada's Intellectual Strength and Weakness* (1893); *Builders of Nova Scotia* (1900); and *Lord Elgin* (1906). For his services Bourinot received academic honors from Laval University, and in 1898 he was decorated as K.C.M.G. See CANADIAN LITERATURE.

BOURKE, R.S., Sixth EARL OF MAYO. See MAYO.

BOURMONT, bōōr'mōn', LOUIS AUGUSTE VICTOR DE GHAISNES, COMTE DE (1773-1846). A French marshal. He was born Sept. 2, 1773, at Château de Bourmont in the department of Maine-et-Loire. Bourmont fought against the Republic under Condé and after 1784 in the struggle in La Vendée. Later he was sent to represent the antirevolutionary party in England. In 1799, when the insurgents in La Vendée had surrendered, Bourmont reappeared and set himself at the head of a guerrilla band, but after some brilliant successes was forced to capitulate. He soon after won the favor of the First Consul, but, becoming suspected of intrigue, was imprisoned at Besançon, whence he escaped to Portugal. When Lisbon was taken by Junot, Bourmont offered his services and, on a pledge of good faith from Junot, reentered France and received successive commissions from Napoleon until he became general of a division. During Napoleon's final struggle Bourmont vacillated and proved inconstant to Louis and Napoleon by turns. After Waterloo he received military employment under Louis XVIII, was Minister of War in 1820, and in the Algerian campaign of 1830 was made marshal. After the July Revolution he served for a brief time under the King of Portugal. He died at Bourmont, Oct. 27, 1846.

BOURNE, EDWARD GAYLORD (1860-1908). An American historian, born at Strykersville, N. Y. In 1883 he graduated with high honors at Yale, where he became professor of history in 1895. He published many critical papers on historical subjects, a number of which have been collected in a volume, *Essays in Historical Criti-*

cism (1901, 1913) They are good examples of painstaking research and the critical sifting of evidence, and one of them, "The Legend of Marcus Whitman," aroused widespread discussion and is generally considered to have settled the Whitman question (See WHITMAN, MARCUS) Professor Bourne also published *The History of the Surplus Revenue of 1837* (1885), *Historical Introduction to the Philippine Islands* (1903), *Spain in America* (1904), *Life of J. L. Motley* (1905), *Discovery, Conquest, and History of the Philippine Islands* (1907), besides editing *Roche's Spanish Colonial System* (1904) and translating *The Narrative of De Soto* (1904) and *The Voyages of Champlain* (1905)

BOURNE, GEORGE (1780-1845) An American clergyman He was born at Westbury, Wiltshire, England, visited the United States in 1802 and again in 1804, and after remaining for some time in Baltimore, settled at Harrisburg, Va There he established a printing office and did everything in his power to educate the people in his pastorate He early made himself conspicuous by advocating immediate abolition of slavery In 1815 he organized a church of non-slaveholders, and wrote a work on *The Book and Slavery Irreconcilable* (1815) His views were ultraradical for the time and brought him into constant difficulties, which led him to give up his printing office and church and move to Germantown, Pa From there he went to Sing Sing, now Ossining, N Y, then to Quebec, and finally to New York City, where he founded a paper called *The Protestant Vindicator* His works include *Lectures on Ecclesiastical History* (1822), *Pictures of Quebec* (1830), and *Slavery Illustrated in its Effects upon Women* (1834)

BOURNE, HUGH (1772-1852) The founder of the sect of Primitive Methodists He was born April 3, 1772, at Fordhays Farm, parish of Stoke-on-Trent, Staffordshire, England Originally a preacher among the Wesleyan Methodists, he distinguished himself by the fervor of his religious sentiments and by the zeal which he displayed for the conversion of the ungodly His enthusiasm for "revivals" and open-air meetings, however, received no countenance from the leading clergymen of the denomination to which he belonged, and in 1808 Bourne was cut off from the Wesleyan connection He was not, however, alarmed His preaching was wonderfully acceptable, and he quickly gathered round him many devoted adherents In March, 1810, a committee of 10 members was formed This may be regarded as the first official organization of the body The first general meeting of the society occurred the next year, and the name "Primitive Methodists" was adopted in 1812 The opprobrious name "Ranters" was given to them by their opponents In 1823 Bourne published *History of the Primitive Methodists*, a narrative of his labors and those of his coadjutors, and in 1824 founded *The Primitive Methodist Magazine*, which he edited for 20 years In the course of his life he visited Scotland, Ireland, Canada, and the United States, where his ministrations were attended with great success He died at Bemersley, in Staffordshire, Oct 11, 1852 For his biography, consult J Walford, *Memoirs*, of which only vol 1 appeared (London, 1855)

BOURNE, JONATHAN, JR (1855-) An American legislator, born in New Bedford, Mass He entered Harvard University in the class of 1877, but left college before graduation to go to

sea He was shipwrecked off the island of Formosa and was picked up and taken to a port of Oregon Thereafter he practiced law for a time, then, engaging in mining and commercial enterprises, became president of many corporations in Oregon and other States, and finally identified himself actively with Republican politics He was a member of the Oregon House of Representatives in 1885, 1896, and 1897, and in 1907 was elected to the United States Senate for the term ending 1913 Although up to this time noted rather for conservatism than radicalism in politics, he soon became one of the foremost advocates of the initiative, referendum, recall of public officials, and direct election of senators In spite of the approval which these radical measures are accorded in Oregon, Senator Bourne was defeated for nomination for reelection in 1912 During his last year in the Senate he was chairman of the Post Office Committee and had much to do with the enactment of the law providing for the parcel post

BOURNE, VINCENT (1695-1747) An English poet He studied at Westminster School, entered Trinity College, Cambridge, in 1714, and was appointed usher in Westminster School He died Dec 2, 1747 Bourne is remembered for a volume of Latin poems published in 1734 It reached a third and enlarged edition in 1743 Of Bourne, Cowper wrote extravagantly "I think him a better Latin poet than Tibullus, Propertius, Ausonius, or any of the writers in his way, except Ovid, and not at all inferior to him" Several of his poems were translated by Cowper, and by Charles Lamb, who likewise admired them greatly Their charm lies in their simplicity and grace They are marked, too, by a quiet pathos Special attention may be called to his epitaphs Consult *Poemata*, ed Mitford (London, 1840)

BOURNEMOUTH, bōrn'mūth A watering place and winter health resort on the south coast of England in Hampshire, about 30 miles west-southwest of Southampton, on Poole Bay (Map England, E 6) On account of its sheltered position, surrounding pine woods, and even temperature, it has become a favorite winter resort for persons suffering from pulmonary diseases The town received its charter of incorporation in 1890 A sanitarium for consumptives was erected in 1895, and there is also a home for convalescents Bournemouth maintains several parks and winter gardens and a golf course It has churches, hotels, a library and reading room, and assembly rooms, baths, and a pier 800 feet long Pop, 1911, 78,677

BOURNONITE, bōrn'on-īt (after Count Bournon, the discoverer) A lead-copper sulphantimonite that crystallizes in orthorhombic forms of considerable complexity, a common form of crystal resembling a cogged wheel from which is derived the common name of "wheel ore" It has a metallic lustre, is of a steel-gray color, and is found both massive and in crystals The chief localities are the Harz Mountains, Bohemia, Chile, Mexico, and, in the United States, various places in Arizona, Arkansas, and Colorado

BOURNOUS, bŭr-nōōs' See BURNOOSE

BOURRÉE, bōrr'ā' An old French dance, originated in the province of Auvergne towards the end of the sixteenth century It is in lively alla breve time, and invariably begins on the up beat In form it is binary, each part being repeated It frequently constitutes one of the movements in the older suite (qv) Each often

introduces a second bourrée, after which the first is repeated. Thus it is treated very much like the trio of the minuet (q.v.).

BOURRELET, böör'lét' (Fr. a stuffed cap, worn by children; dimin. of *bourre*, hair, wadding). In elongated projectiles with a pointed head, the imaginary line around the projectile at the junction of the cylindrical body and ogival head.

BOURRIENNE, böör'yén', LOUIS ANTOINE FAUVELET DE (1769-1834). The secretary and early friend of Napoleon I. He was born at Sens, July 9, 1769. He was educated at the military school at Brienne, where he formed an intimate friendship with Napoleon. The latter, as his influence grew, rapidly advanced Bourrienne, whose avarice, however, brought him into disgrace. Notwithstanding this, he was sent, in 1804, as chargé d'affaires to Hamburg, where he was commissioned to watch over the strict enforcement of the Continental System, but was recalled and obliged to restore a million francs which had been removed by him from the public funds (1810). In revenge, he espoused the cause of Louis XVIII, and he zealously served the Bourbons until the July Revolution. After this his reason failed him, and he died in an asylum at Caen, Feb. 7, 1834. His memoirs concerning Napoleon, the Directory, the Consulate, the Empire, and the Restoration (*Mémoires sur Napoléon*, etc., 10 vols., Paris, 1829) gave many new explanations of the events of the time, but are in many respects untrustworthy. (See **BOULAY DE LA MEURTHE**.) A work entitled *Histoire de Bonaparte par un homme qui ne l'a pas quitté depuis 15 ans* has been erroneously ascribed to him.

BOURSALT, böör'sá', EDMÉ (1638-1701). A French satirist and dramatist. Boursault won the favor of Louis XIV by his *Véritable étude des souverains*, a book written for the education of the Dauphin. His dramas, *Esope à la cour* and *Esope à la ville*, were very popular; his tragedies highly esteemed by the enemies of Racine. His *Le portrait du peintre*, an attack on Molière for his *Ecole des Femmes* provoked from Molière the caustic *Impromptu de Versailles*, where Boursault figures by name, as he did in early editions of Boileau's satires in response to his *Satyres des Satyres*. Later Boursault did Boileau a kindness, and his name was erased from that roll of dishonor. Consult Saint-René Taillandier, *Études littéraires* (Paris, 1881).

BOURSE, böörs. See EXCHANGE; STOCK EXCHANGE.

BOUSSA, böös'sá. See BUSSANG.

BOUSSET, WILHELM (1865-). A German New Testament critic and historian of religion. He was born in Lübeck, studied there, at Erlangen, Leipzig, and Göttingen, and in 1899 received the degree of doctor of theology at Heidelberg. He became professor of New Testament exegesis at Göttingen in 1896, and one of the editors of the *Theologische Rundschau* in 1897 and of *Forschungen zur Religion und Literatur des alten und neuen Testaments* in 1903; and he contributed to the *Zeitschrift für neutestamentliche Wissenschaft* and the *Encyclopaedia Biblica*. His writings on religious and church history deal especially with apocalyptic eschatology and Gnosticism. Among his books are: *Jesu Predigt in ihrem Gegensatz zum Judentum* (1892); *Textkritische Studien zum neuen Testament* (1894); *Antichrist* (1894; Eng. trans., 1896); in the

Meyer's series a *Kommentar zur Offenbarung Johannis* (1896; 2d ed., 1906); *Die Religion des Judentums in neutestamentlichen Zeitalter* (1903); *Das Wesen der Religion* (1903; 3d ed., 1905; trans. into English, Swedish, Dutch, Hungarian); *Hauptprobleme der Gnosis* (1907); and *Die Bedeutung der Person Jesu für das Glauben* (1910; Eng. trans., 1911). Bousset was active in the Christian Socialist movement. In 1913 his *Faith of a Modern Protestant* was published in New York.

BOUSSINGAULT, böös'sán'gó', JEAN BAPTISTE JOSEPH DIEUDONNÉ (1802-87). A French chemist, distinguished for investigations in agricultural chemistry. He was born in Paris and was educated at the School of Mines of St. Etienne. In the employment of an English mining company he went to South America, where, besides rendering important professional services, he served under General Bolívar in the South American war of independence. On his return to France he was appointed professor of chemistry at Lyons. In 1839 he became a member of the Institute and was appointed to the chair of agriculture in the Conservatoire des Arts et Métiers, in Paris. In 1857 he was made commander and in 1876 grand officer of the Legion of Honor. Boussingault published a large number of valuable papers embodying the results of his experimental investigations on various topics in general chemistry and particularly in agricultural science; a collection of his more important memoirs appeared in 1854. Among his highly valuable publications may be mentioned his *Economie rurale* (2 vols., 1844), which was republished in enlarged form under the title *Agronomie, chimie agricole et physiologie* (8 vols., gradually published, and partly republished, between 1860 and 1891); this work was translated into English and German and won for its author a European reputation.

BOUSSU, böös'sü'. A town in the province of Hainaut, Belgium, situated about 7 miles west of Mons, with which it is connected by rail (Map; Belgium, B 4). It contains foundries and smelting works and in its vicinity are extensive coal mines. It was the scene of two engagements between the Austrians and the French on April 28 and on Nov. 4, 1792. Pop., 1900, 10,900; 1910, 11,690.

BOUSTROPHEDON (Gk. βουστροφῆδον, *boustrophēdon*, from *bois*, *bous*, ox + *strophēai*, *strophēin*, to turn). A word descriptive of a method of writing common among the Greeks of the sixth century B.C., in which the lines were written alternately from right to left and from left to right, or conversely. The method took its name from its resemblance to the winding course taken by oxen in plowing and was transitional between the earlier method, wherein the lines all ran from right to left, and the later method, wherein they all ran from left to right. (See WRITING.) Consult E. S. Roberts, *An Introduction to Greek Epigraphy*, part i (Cambridge, 1887).

BOUTARIC, bööt'ár'ek', EDGAR PAUL (1829-77). A French historian, born at Châteaudun (Eure-et-Loir). He was appointed chief of the administrative section of the national archives, whose original documents he utilized in preparing his historical studies, which are distinguished by critical care. They deal chiefly with French institutions of the Middle Ages and include *La France sous Philippe le Bel* (1801); *Institutions militaires de la France avant les*

armées permanentes (1863), *Saint Louis et l'Alphonse de Poitiers* (1870), and other important works. Consult Bruel and Bonnasieux, *Edgar Boubouroche* (Paris, n.d.).

BOUTEL', Mrs. An English actress of the latter half of the seventeenth century. The facts of her life are to a great extent unrecorded, but she appeared at Drury Lane, then the Theatre Royal, about 1663, and before she retired from the stage in 1696 had for years been a popular actress in the London theatres, playing frequently with Betterton, Mrs. Barry, and Mrs. Bracegirdle (q.v.). She was famous, according to an old writer, for her happy presentation of the character of the "young innocent lady whom all the heroes are mad in love with," a part for which her personal charms well fitted her. Among her rôles were Aspatia, in *The Maid's Tragedy* (1666), Melantha, in *Marriage à la mode* (1672), Mrs. Pinchwife, in *Wycherley's Country Wife* (1673), Rosalinda, in *Sophonisba* (1676), Cleopatra, in *Dryden's All for Love* (1678), and Mrs. Termagant, in *The Squire of Alsatia* (1688). Her success on the stage enabled her to retire with a competence before she reached old age. Consult Genest, *History of the English Stage*, vol. II (Bath, 1832), and Doran, *Annals of the Stage*, ed. Lowe, vol. I (London, 1888).

BOUTELL, HENRY SHERMAN (1856-) An American diplomat, born in Boston, Mass., and educated at Northwestern and Harvard universities. He engaged in the practice of law at Chicago, was a member of the Illinois House of Representatives in 1884, and, from 1897 to 1911, when defeated for reelection, was a member of Congress. On March 2, 1911, he was appointed Minister to Portugal, but several weeks later Switzerland was made his destination. During his service in Congress he was one of the most efficient of Republican members and was on many important committees. In 1899 he was president of the Phi Beta Kappa Society and in 1904 received the degree of LL.D. from Northwestern University. On Jan. 2, 1913, he resigned as Minister to Switzerland to accept a seat on the Court of Claims bench.

ROUTELE, bou-têl', CHARLES ADDISON (1839-1901). An American journalist and politician, born at Damariscotta, Me. He entered the merchant marine, enlisted in the United States navy in the South Atlantic blockading squadron in 1862, and in command of the *Nyanza*, with rank of lieutenant, participated in the capture of Mobile. In 1870 he became managing editor, and in 1874 proprietor, of the *Bangor Whig and Courier*. He was a delegate to Republican national conventions in 1876, 1880, 1884, and 1888, and was a member of the National House of Representatives from the Forty-eighth to the Fifty-third Congress (1880-1901). He was particularly active as a member of the House committee on naval affairs, of which he was chairman in the Fifty-first, Fifty-fourth, and Fifty-sixth Congresses, and did much to promote the construction of the new United States navy.

BOUTERWEK, bōt'ēr-vêk, FRIEDRICH (1766-1828). A German philosopher and æsthetic writer, born near Goslar, in the Harz region. He at first studied law at Göttingen, but soon devoted his whole energies to the study of philosophy and of the history of literature. In philosophy he was at first a zealous follower of Kant, but afterward inclined more towards

Jacobi. He began to give lectures in Göttingen in 1791 and became professor of philosophy in 1797. Of his philosophical writings, *Ideen zu einer allgemeinen Ästhetik* (2 vols., 1799) is the most important, but his great work, on which his reputation really rests, is his *Geschichte der neuen Poesie und Beredsamkeit* (9 vols., Göttingen, 1801-12). The part relating to Spanish literature is especially valuable and has been translated into Spanish and much enlarged by José Gómez de la Cortina and Nicolás Hugel de Molinedo (3 vols., Madrid, 1828). A portion of it was also translated into English and published under the title *History of Spanish Literature* (1823). His writings also include three novels, *Paulus Septimus* (1795), *Graf Donamar* (1791), and *Ramiro* (1804), *Ästhetik* (2 vols., 1806), *Kleine Schriften*, with his autobiography (1818).

BOUTET DE MONVEL, LOUIS MAURICE See MONVEL, LOUIS MAURICE BOUTET DE

BOUTMY, bōt'mé', EMILE (1835-1906). A French publicist, born in Paris. He was for a time a journalist, and from 1865 to 1869 occupied the chairs of the history of civilization and of the comparative history of architecture at the École Spéciale d'Architecture. He assisted in founding the École Libre des Sciences Politiques (1872), where for a number of years he held the chair of comparative constitutional history. He was elected a member of the Academy of Moral and Political Sciences in 1898. He published several excellent works, including *Introduction au cours d'histoire comparée de l'architecture* (1869), *Études de droit constitutionnel. France, Angleterre, États-Unis* (1885), *Développement de la constitution en Angleterre* (1886), *Les Latins* (1894), *Essai d'une psychologie politique du peuple anglais au XIX^e siècle* (1901, Eng. trans., 1904), *Éléments d'une psychologie politique du peuple américain* (1902).

BOUTO, bō'tō, or INJIA A blackish or reddish porpoise-like dolphin (*Ima geoffroyensis*, or *geoffroyensis*), about 7 or 8 feet long, which abounds in the rivers of the Amazon valley, going far towards their heads. The color variations are extraordinary, some individuals being wholly pink, others black above and pink below. See DOLPHIN, TUCUXI.

BOUTROUX, bōt'rōs', ETIENNE EMILE MARIE (1845-) A French philosopher and professor at the University of Paris. He was born at Montrouge (Seine). In 1912 he was elected to the French Academy and in 1913 received an LL.D. from Princeton University. His doctrine rests upon an analysis of logical and of causal necessity and in the distinction between the point of view of quality and that of quantity. Of these two points of view, the former permits us to perceive only permanency, immobility, and fatality, while the latter enables us to distinguish motion, finality, contingency, and progress. Boutroux also published vols. I and II (1877 and 1882) of a translation of the *Philosophie der Griechen*, by Eduard Zeller, *De la contingence des lois de la nature* (1874, 6th ed., 1907), *De l'idée de loi naturelle dans la science et la philosophie contemporaines* (1895, Eng. trans., 1911), *Questions de morale et d'éducation* (1895, 4th ed., 1905), Eng. trans. by Fred Rothwell, as *Education and Ethics* (1913), *Pascal* (1900, 4th ed., 1907, Eng. trans., 1902), *William James* (1911, 2d ed., 1912, Eng. trans., London, 1912), *Henri Poincaré* (1913).

BOUTS, bouts, **DIERICK** (Dieric) (also called in English Dirk, and Thierry Bouts, after the French) (c.1420-75). One of the most prominent and influential painters of the early Netherlandish school. The year of his birth at Haarlem is variously conjectured from 1400 to 1420, the latter date being the most likely. In this case he may well have studied at Brussels with Rogier van der Weyden (q.v.), whose paintings his earliest productions most resemble; as, for example, the "Crucifixion" in the Berlin Museum. The data concerning his life are very meagre. Before 1447, the year of his first marriage, he had settled at Louvain. In 1468 he was named town painter by the town council, which visited his studio in state. He married a second time in 1475 and died May 6 of the same year. He has been wrongly confused with Steurbouts, a contemporary painter of Louvain. Little was known of his art until modern research cleared up the problem. The contract still survives for his masterpiece, the altar of the Chapel of the Sacrament, St. Peter's, Louvain (1464-68)—one of the greatest products of the early Netherlandish school. The central panel, "The Last Supper," is still in its original place. But of the four paintings which adorned the two wings, two, "Abraham and Melchizedek" and the "Fall of Man," are in the Munich Pinakothek; "Elijah in the Desert" and the "Feast of the Passover" in the Museum of Berlin. In St. Peter's, also, is a second important altar by him, representing the "Martyrdom of St. Erasmus" with Sts. Jerome and Bernard on either wing. Of his pictures for the Town Hall of Louvain, two survive in the Brussels Gallery, "The Unjust Judgment of Emperor Otho III" and the "Punishment of the Guilty Empress." Among other important paintings now attributed to him are: "The Martyrdom of St. Hippolytus," in St. Sauveur, Bruges; three panels in the Capilla Real, cathedral of Granada, "The Birth of Christ" (National Gallery, London) and the "Bewailing of Christ's Body" (Louvre), both formerly ascribed to Rogier van der Weyden, and an admirable portrait in the National Gallery said to represent the painter himself.

Bouts surpasses all of his contemporaries in color. He was the first to substitute for the bright sharp tints of the early Flemish school a softer and more subtle color scheme, based upon tone. He excelled also in composition and in representing space and atmosphere as well in the interiors as in his admirable landscapes, but he was deficient in the anatomy of his figures, which he sought to atone for by impressive countenance and gesture. This psychical expression is one of the chief charms of his pictures. After Jan van Eyck he was the most influential figure in the art of the Netherlands in the fifteenth century. Among the important painters directly influenced by him were Hugo van der Goes, Hans Memling, Gerhard David, and Quentin Metsys (q.v.). His sons, **DIERICK THE YOUNGER** and **ALBRECHT** (died 1549), continued their father's work. Consult Friedländer, *Meisterwerke der niederländischen Malerei der 15 und 16 Jahrhunderte*; Heiland, *Dirk Bouts und die Hauptwerke seiner Schule* (Strassburg, 1902); Hymans, *Gazette des Beaux-Arts* (Paris, 1902); Voll, *Die alt-niederländische Malerei* (Munich, 1906); Pierson-Gevaert, *Les primitifs Flamands* (Brussels, 1908).

BOUTS-RIMÉS, bōō'rè-má' (Fr. rhymed

endings). A kind of verse, the making of which has formed a social amusement since 1648, when a French poet introduced the diversion. Some one of the party gives out the rhymes or endings of a stanza, and the others have to fill up the lines as they best may. Suppose the rhymes prescribed are *wave, lie; brave, die*; the following is one of the ways in which the lines might be completed:

Dark are the secrets of the gulph	wave,
Where, wrapped in death, so many heroes	lie;
Yet glorious death's the guardian of the	brave,
And those who bravely live can bravely	die.

Addison ridicules the amusement in the *Spectator*, No. 60, but in French, *bouts-rimés* have been seriously composed,—the most classic instance being that of the sonnets of Etienne Mallemaens, who in 1701 wrote them on the basis of rhymes furnished him by the Duchesse du Maine.

BOUTWELL, GEORGE SEWALL (1818-1905). An American politician and cabinet officer. He was born in Brookline, Mass., was admitted to the bar in 1836, and between 1842 and 1851 was seven times chosen to the Massachusetts Legislature. Thenceforth he was a leader of the Democratic party in his State, was chosen Governor in 1851, and was reelected the next year. On the repeal of the Missouri Compromise in 1854, he left the Democratic and assisted in the organization of the Republican party. In 1862, as commissioner, he organized the new Department of Internal Revenue; in 1863 was elected to Congress, and was twice rechosen. In 1868 he was one of the managers of the impeachment of President Johnson, from 1869 to 1873 was Secretary of the Treasury, and in the latter year was elected United States Senator. In the financial business of the government he had a large share of influence and responsibility. In 1877 he was appointed by President Hayes to prepare a codification of the statutes-at-large. The result was the second edition of the *United States Revised Statutes* (1878). He was an overseer of Harvard and secretary of the Massachusetts Board of Education, and he prepared many valuable reports. In 1900 he was chosen president of the Anti-Imperialist League. He published *Educational Topics and Institutions* (1859); *Manual of the United States Direct and Revenue Tax* (1863); *The Tax-Payer's Manual* (1865); *Speeches and Papers* (1867); *The Constitution of the United States at the End of the First Century* (1895); *The Crisis of the Republic* (1900); *Reminiscences of Sixty Years in Public Affairs* (1902).

BOUVARDIA, bōō-vār'di-á (named in honor of Bouvard, physician to Louis XIII and superintendent of the Royal Gardens in Paris). A genus of 20 or 30 species of American shrubs or perennial herbs, mostly Mexican, of the family Rubiaceae. Bouvardias are cultivated to a considerable extent as late fall or early winter greenhouse plants. The red or white flowers are long and tubular, four-lobed, and contain four stamens. The fruit is a two-celled capsule. *Bouvardia triphylla* in some of its cultural forms is a favorite in borders, producing flowers from June till November.

BOUVART, or **BOUVARD**, bōō-vār', **ALEXIS** (1767-1843). A French astronomer. He was born at Les Contamines in Haute Savoie. In 1804 he was a member of the Bureau of Longitudes. He assisted Laplace in the *Mécanique*

céleste and became a member of the Academy and director of the Observatory. Bouvet discovered eight comets and was the first to point out the irregularities of the planet Uranus. The investigation of these irregularities led to the discovery of Neptune by Leverrier and Adams in 1846. He published *Nouvelles tables de Jupiter et de Saturne* (1808) and *Mémoire sur les observations météorologiques faites à l'Observatoire de Paris*.

BOUVET, bōv'vā', JOACHIM (c1662-1732) The founder of the French Jesuit Mission in China, biographer of the famous Manchu Emperor Kang-hi, and initiator of the first survey, by the Jesuits, of the Chinese Empire, which is still the basis of our maps. He was born at Mons, in Belgium. Louis XIV directed him and five other learned Jesuits, including Gerbillon, to proceed to China. They arrived there in July, 1686, and were graciously received by the Chinese Emperor. They succeeded so well in the architectural enterprises committed to them that Kang-hi permitted a church and residence to be built for them inside the Tatar city. The first treaty ever signed by the court of Peking, with the Russians, for trade, definition of frontier, and their evacuation of Albazin and Manchuria, was negotiated largely through the influence of these missionaries. In 1696 Bouvet was commissioned to bring out from France other missionaries, and in 1699 he returned with 10 fellow-Jesuits, among them the learned Parennin, and the survey of the Empire was begun. Bouvet wrote a biography of Kang-hi and an account in four languages of his various travels, besides his book, *État présent de la Chine, avec figures gravées par Griffart* (1697). On the basis of the concessions to Bouvet and Gerbillon, the French laid claims in the Treaty of Tientsin to the land and the rebuilding at Chinese expense of the great Pei Tang or Northern Cathedral in Peking, destroyed by the Boxers. Consult Michie, *The Englishman in China*, vol. viii (Edinburgh, 1900), and Smith, *China in Convulsion* (New York, 1901).

BOUVIER, bōv'vā', AUGUSTE AMI OSCAR (1826-93) A Swiss Protestant theologian. He was born in Geneva and studied at the University of Berlin (1846), and Geneva (1847-51). He was engaged in evangelical work in Paris (1853) and later went to London, where he became pastor of the Swiss church. He occupied the pulpit in the Quartier Saint-Gervais at Geneva in 1857, and four years afterward was appointed professor of practical theology at the Geneva Academy. During his visit to Germany he became strongly influenced by the views of Schleiermacher, Neander, and others, and in his works, which are characterized by scholarly research and independence of thought, he favors the gradual adoption of the principles of modern liberalism by the Evangelical party. His principal works are the following: *Époques et caractères bibliques* (1873), *Le pasteur John Bost* (1882), *Paroles de foi et de liberté* (2 vols., 1882-85), *Théologie systématique* (1887), *Étude sur la prédication de Jésus* (1892).

BOUVIER, JOHN (1787-1851) An American jurist. He was born at Codogno, Italy, but his family emigrated to America in 1802, and he was brought up in Philadelphia. In 1822 he began to practice law there and in 1838 became associate judge of the Court of Criminal Sessions. Among his publications are a valuable

Law Dictionary Adapted to the Constitution and Laws of the United States of America, and of the Several States of the American Union (1839, rev ed by F Rawle, 1897), a new ed. of *Bacon's Abridgment of the Law* (10 vols., 1841-45), *The Institutes of American Law* (4 vols., 1851), his greatest work.

BOUVINES, bōv'vèn' (anciently, Lat *Bovinum*) A small French village near Lille in France and Tournay in Belgium, noted as the scene of a victory won by Philip Augustus on July 27, 1214. Otho IV of Germany had appealed to John of England for aid against Frederick II, who was claiming the Imperial crown, the latter had made an alliance with France. Otho and John planned a double attack upon Philip Augustus. John invaded the Loire country unsuccessfully, Otho attacked the north and met the French army at Bouvines. With Otho were some vassals of Philip Augustus, including the Count of Flanders and the Count of Boulogne, some Imperial vassals, including the Count of Holland and the Duke of Brabant, and an English contingent led by William Longsword, Earl of Salisbury. The French won by superior tactics. Otho IV of Germany, defeated and crushed, lost his power, and Frederick II was soon recognized as Emperor. The possession of Normandy, Maine, Anjou, Touraine, and Poitou was assured to Philip, and this victory made a united France possible. England also became more unified after the loss of these French provinces. In its far-reaching consequences this was one of the most important battles of the Middle Ages. Consult Oman, *History of the Art of War*, vol. i, pp 461-477 (London, 1898).

BOVARY, bō'vā'rē', MADAME See MADAME BOVARY.

BO'VATE (from Lat *bos*, ox, *cow*), or OX-GANG In the mediæval manor, the space of land an ox could plow in a year, one-eighth of the carucate (q.v.). Often stated as 18 acres.

BO'VEY, HENRY TAYLOR (1853-1912) An English engineer, born in Devonshire, England. Following a Cambridge University education he spent several years in travel, and then became assistant engineer on the Mersey docks and harbor works. In 1887 he was appointed professor of civil engineering at McGill University (Canada) and on the establishment of a department of science in that institution was made dean. His publications include *Applied Mechanics* (1882), *Theory of Structures and Strength of Materials* (1893, 4th ed, 1904), *A Treatise on Hydraulics* (1895, 2d ed, 1901), *A New Extensometer* (1902), *Unification in Education* (1908).

BO'VEY COAL See LIGNITE.

BO'VIA'NUM The name of two ancient towns of Samnium. 1 Bovianum Vetus, capital of the Caraceni, conquered by the Romans in 298 B.C., now Pietrabbondante, near Agnone. Among the ruins are portions of a temple and a theatre (with three rows of seats well preserved), some Oscan inscriptions have been found on the site. 2 Bovianum Undecimanum, now Boiano, capital of the Pentri, conquered by the Romans in 311 B.C., it served as their headquarters in the Second Punic War, and as a confederate headquarters in the Social War until taken by assault by Sulla in 89 B.C. It was called Undecimanum because Vespasian established there the veterans of the Legio Undecima Claudia.

BOVIDÆ (from Lat. *bos*, gen. *bovis*, ox). A family of ruminants embracing all those having hollow persistent horns in both sexes (save in certain antelopes), combined with certain other anatomical characters. (See RUMINANT.) It includes the domestic animals that "chew the cud," and others prominent as game. These are usually divided into five subfamilies or sections, viz. (1) antelopes (*Antilopinae*); (2) goats (*Caprinae*); (3) sheep (*Ovinæ*), (4) musk oxen (*Ovibovinae*); (5) oxen (*Bovinae*). In a general way, and by typical examples, these divisions (elsewhere fully treated under their English names) are easily recognized; but when all the representatives of the family are considered, they are found to intergrade confusingly, so that some naturalists regard the sub-sections of antelopes (as the Alcephaline, etc., see ANTELOPE) as coordinate with the Caprinae, Ovinæ, etc., and opinions vary as to their interrelations: while certain forms, especially the saigas, are by some authorities excluded altogether. Some 35 genera are recognized, of which 24 are African. The most conspicuous common character is the nature of the horns, which occur in pairs and consist of hollow sheaths of hardened and thickened epidermis (see HORN), covering and supported by bony outgrowths of the skull, varying in form in the different groups. These begin to grow soon after birth, enlarging with the growth of the core, and are perfected at maturity, at which time "the core becomes excavated by the extension into it of the frontal sinuses, whence the ruminants which possess such horns are not infrequently called *Caricornia*"; once assumed, they remain permanently throughout life, forming the principal weapons of offense and defense possessed by the tribe. The distribution of the family is extensive, covering all of the Old World except Australasia, but in the Western Hemisphere it is confined to the northern continent, none being indigenous to South America. Most of them, however, show high adaptability for acclimatization, enabling the domesticated species to thrive in almost every part of the world.

BOVINO, bō-vē'nō (anciently, Lat. *Vebinum*). An episcopal city in the province of Foggia, south Italy, 2100 feet above the sea, and 20 miles southwest of Foggia (Map: Italy, K 6). It has an ancient cathedral and the ruins of an aqueduct. Its chief trade is in wine and oil. Pop., 1881 (commune), 7784; 1901, 7613; 1911, 8009.

BOW. See ARROW.

BOW (AS. *boga*, a bow to shoot with, because it is bent or bowed, cf. Ger. *Bogen*, bow, from *beugen*, to bend). A slender piece of elastic wood, with slight lateral projections at the ends between which is stretched a quantity of horse-hair, used to set into vibration the strings of instruments of the violin class. The oldest instrument played with the bow is the *rebec* (q.v.). The stick forming the bow was at first greatly curved, and a string, or cord, was tied from one end to the other. As the earliest figure of the bow is found in the Anglo-Saxon manuscripts, it is thought to be of British origin, and may have been used in the sixth century with the *oroth*, but this is not certain. The bow has been subject to various changes, the most significant of which were effected by Corelli (q.v.), until François Tourte (1747-1835) brought the art of bow making to perfection and created a model which has given him the

name of the "Stradivarius of the bow." This combines all qualities to follow every degree of tone and expression—lightness, firmness, power, and elasticity. Tourte fixes the length of the violin bow at 29-29½ inches; that of the viola at 29 inches, and that of a 'cello at 28½-28¾ inches. The stick is usually of Brazilian lancewood, or snakewood, cut to follow the grain, and slightly bent inward by exposure to heat. The nut is of ebony, or tortoise shell, and contains a screw by which the hair may be tightened or loosened. From 80 to 250 hairs from the tails of horses are used, white for the violin, viola, and violoncello, and black for the double bass. The friction is increased by application of rosin to the hair. For a brief but interesting account of the history and construction of the bow, consult Heron-Allen, *Violin-Making as It Was and Is* (London and New York, 1884).

BOW, bou (same word as *bough*, AS. *bōg*, bough, shoulder, Icel. *bögr*, shoulder), or a SHIP. A general name for the fore part, or that which breasts the waves. Very often the word is used in the plural, the ship being considered to have starboard and port, or right and left, bows, meeting at the prow or figurehead. A *narrow* or *lean* bow, and a *broad* or *bluff* bow, are seamen's phrases for different shapes of bow, each of which has its own peculiar advantage at sea; the narrow bow will cut more smoothly through the water, but a broad bow bears up more firmly in a high sea. Other forms are the *overhanging* bow, *receding* or *ram* bow, *clapper* bow, *flaring* bow, etc. "On the bow" in sea language, is the position of a distant object when seen over the bow; it implies a sweep of one-quarter of the horizon, embracing about 45° on each side of the prow or head. See BEARING; SHIPBUILDING.

BOW (bō) CHINA. A peculiar kind of porcelain, manufactured originally in England, at Stratford-le-Bow, whence the name. It is of a fine, milky-white color and is decorated with imitations of Chinese figures. Many pieces are colored in the style of Dresden china, and a characteristic decoration is a sprig of hawthorn in high relief. There were also reproduced a number of statuettes or small groups of figures modeled more or less upon German designs. The marks on Bow porcelain are usually an arrow, an anchor, a dagger, or a bow and arrow. Bow china dates from 1744, when Edward Heylyn and Thomas Frye obtained a patent for the manufacture of porcelain at Bow. They used an American clay called *unaker*, "the produce of the Cherokee Nation," which seems to have been a kind of kaolin. After grinding and washing to separate the sand and mica, powdered glass was added to the clay in proportions varying from equal parts of clay and glass to one-fifth of glass. The later Bow porcelain sometimes contained as much as 40 per cent of bone ash. For the glaze, which was a similar mixture, less of the clay was used. In 1748 Heylyn and Frye obtained another patent for a softer kind of porcelain, which was characterized by a more fusible lead glaze in which *unaker* was not used at all, but a pipe clay instead. In 1750 Messrs. Weatherly and Crowther obtained possession of the Bow works and gave them the name of New Canton. The works succeeded for a time, employing 300 operators; in 1763 Crowther, the sole surviving partner, became bankrupt, but he continued to carry on the business till 1775. In that year William Duesbury bought the Bow

works and transferred them to Derby Consult Bemrose, *Bow, Chelsea, and Derby Porcelain* (London, 1898), Wallis, *Pottery Porcelain of Derbyshire* (London, 1870), Nightingale, *Contributions toward the History of Early English Porcelain* (Salisbury, 1881), Church, *English Porcelain A Handbook* (London, 1885) See POTTERY

BOWDITCH, bou'dich, THOMAS EDWARD (1791-1824) An English traveler and writer, born in Bristol, England. He was for some time a publicity agent in the service of the African Company, but was selected in 1815 to conduct a mission to the King of Ashantee, of which he published an account in 1819, under the title, *A Mission from Cape Coast Castle to Ashantee*. On his return to Europe he published the *African Committee* (1819), which by its exposures forced the government to take its African possessions into its own hands. He then proceeded to Paris, where he spent several years perfecting himself in mathematics and natural history. To obtain funds for a new expedition into the interior of Africa, he published a translation of Mollien's *Travels in the Interior of Africa to the Source of the Senegal and Gambia* (1820), *Taaiderny* (1820), *British and Foreign Expeditions to Teembo* (1820), and in August, 1822, sailed from Havre. Stopping at Lisbon, he made a careful study of all the Portuguese discoveries, and published a work entitled *An Account of the Discoveries of the Portuguese in Angola and Mozambique* (1824). He died of fever, on the Isle of St. Mary, West Africa.

BOWDITCH, bou'dich, CHARLES PICKERING (1842-) An American archaeologist, born at Boston, a brother of Henry P. Bowditch. After graduating from Harvard University he engaged in business as the director of important manufacturing and commercial interests. Besides 10 pamphlets on Central American archaeology, he published *Mayan Nomenclature* (1906), *Maya Numeration, Calendar and Astronomy* (1910), *Bacon's Connection with the First Folio of Shakespeare* (1910).

BOWDITCH, HENRY INGERSOLL (1808-92) An American physician, a son of Nathaniel Bowditch. He was born in Salem, Mass., and in 1828 graduated at Harvard. After receiving his medical degree at that university in 1832, he spent several years in study in Paris. He was professor of clinical medicine at Harvard from 1859 to 1867, chairman of the Massachusetts State Board of Health from 1869 to 1879, physician at the Massachusetts General Hospital and the Boston City Hospital from 1868 to 1872 and president of the American Medical Association in 1877. He announced a law of soil moisture as one of the principal causes of consumption in New England, and was the first to practice the operation of thoracentesis, or puncturing of the chest cavity, in the case of pleural effusions. He was a member of the National Academy of Sciences. The following are some of his principal publications: *Life of Nathaniel Bowditch* (1865), *The Young Stethoscopist* (1848), *Public Hygiene in America* (Centennial address, Philadelphia, 1876), and translations of *Louis on Typhoid* (1836), *Louis on Phthisis* (1836) and *Mauvorn on Cataract* (1837).

BOWDITCH, HENRY PICKERING (1840-1911) An American physician, born in Boston, a brother of Charles P. Bowditch. He graduated at Harvard in 1861 and served throughout the Civil War, during which he attained the rank

of major of volunteers. He graduated at the Harvard Medical School in 1868. He was professor of physiology at the Harvard Medical School from 1876 to 1906, when he retired and became a pensioner under the Carnegie fund. His writings include *The Growth of Children* (1877), *Is Harvard a University?* (1890), *Advancement of Medicine by Research* (1896), *Hints for Teachers of Physiology* (1899).

BOWDITCH, NATHANIEL (1773-1838). An American astronomer and mathematician, born in Salem, Mass. He showed at a very early age an inclination for mathematics, though he was bled to his father's trade of a cooper and was afterward apprenticed to a ship chandler. He acquired Latin that he might study Newton's *Principia*. He particularly devoted himself to the study of the practical applications of science. He went as supercargo of a merchant ship in several long voyages and added a thorough practical acquaintance with navigation to a theoretical knowledge of it. His work, *The New American Practical Navigator* (1802, 1812), was made the standard authority of the United States Navy Department on the subject of navigation, and under direction of the Secretary of the Navy it was revised in 1880, 1903, and 1911. A new and revised edition of his *Useful Tables from the American Practical Navigator* was also issued in 1912 under orders of the department. He published also an admirable translation of Laplace's *Mécanique céleste* (2 vols, Boston, 1829), to which he added valuable annotations. These works obtained for him marks of honor from scientific societies in Great Britain and led to his being called to the professorship of mathematics and astronomy in Harvard College, which position, however, he declined, in order to enter the executive council of the State. Consult N. I. Bowditch, *Memoir of Nathaniel Bowditch* (Boston, 1839).

BOWDITCH'S PRACTICAL NAVIGATOR A compendium of information for navigators. It contains explanations of all the ordinary methods of determining the ship's position at sea, together with all the tables necessary for using them, also descriptions of instruments used in navigation, methods of making hydrographic surveys, charts, etc. The copyright of this work was purchased by the United States government, and it is now published and issued by the Hydrographic Office, United States Navy. It has been several times revised, and a considerable amount of matter has been added.

BOWDLERISM, bou'dler-iz'm. A term used to denote literary prudery or overnice expurgation. It is so named from Thomas Bowdler (1754-1825), who in 1818 published *The Family Shakespeare* in 10 vols., "in which nothing is added to the original text, but those words and expressions are omitted which cannot with propriety be read aloud in a family." The work had a large sale. Bowdler also "purified" Gibbon. More recently among works that have been absurdly Bowdlerized are the Bible, the *Arabian Nights*, *Don Quixote*, Maupassant's *Bel-Ami*, and (by its own author) "Lucas Malet's" *Sir Richard Calmady* (1901).

BOWDOIN, bou'din, JAMES (1726-90) An American politician. He was born in Boston, of French Huguenot descent, graduated at Harvard in 1745, and was subsequently a representative in the General Court, a State Senator, and a counselor. He was an early opponent of English oppression, and in 1775 was chosen Presi-

dent of the Colonial Council. In 1779 he presided over the Massachusetts Constitutional Convention and in 1785 succeeded John Hancock as Governor. In this capacity he proved his executive ability by his energetic measures in the suppression of "Shays's Rebellion" (q.v.). In 1788 he was a member of the convention that ratified the Federal Constitution. Bowdoin was one of the founders, and the first president, of the American Academy of Arts and Sciences, to which he gave his library. He also left a legacy to Harvard College and was a liberal patron of the Massachusetts Humane Society. The oldest college in Maine has been named after him.

BOWDOIN, JAMES (1752-1811). An American public man and philanthropist, born in Boston, the son of Governor Bowdoin. He graduated at Harvard, studied also at Oxford, and traveled in Europe, returning to America soon after the battle of Lexington. In 1805 he was United States Minister to Spain. He left to Bowdoin College 6000 acres of land and \$1100, the reversion of the island of Naushon, where he had his summer home, a large library and an extensive collection of minerals, paintings, and drawings.

BOWDOIN COLLEGE. The oldest seat of learning in Maine. It was chartered in 1794 by Massachusetts, and was named after James Bowdoin, Governor of Massachusetts, of which State Maine was formerly a part. The college opened at Brunswick, Cumberland County, in 1802, with Joseph McKeen, D.D., a Dartmouth graduate, as its first president. From the Hon. James Bowdoin, the son of Governor Bowdoin, the college received valuable gifts. The present buildings of the college, representing a value of about \$1,000,000, include King Chapel, the Walker Art Building, the Searles Science Building, Memorial Hall, the Hubbard Library, the Hubbard Athletic Building, the gymnasium, the Thomas Worcester Hyde Athletic Building, observatory, and dormitories. The course of study leading to the degrees of A.B. and B.S. is based on a knowledge of the ancient and modern languages and mathematics and includes such other courses as are usually given in smaller colleges of the first class. Connected with Bowdoin College is the Medical School of Maine, organized in 1820. The government of Bowdoin is administered by 13 trustees, the president and treasurer of the institution being ex officio members, and by 40 overseers. Among noted graduates of Bowdoin may be mentioned Nathaniel Hawthorne, Henry W. Longfellow, William Pitt Fessenden, Franklin Pierce, Sergeant S. Prentiss, John P. Hale, Chief Justice Melville W. Fuller, Thomas B. Reed, William P. Fryc, Gen. O. O. Howard, and Rear Admiral R. E. Peary. In 1913 Bowdoin had 82 professors and instructors, 333 academic students, and 72 medical students, and a library of 103,000 volumes. The college is nonsectarian. President, William De Witt Hyde, S.T.D.

BOWELL, bou'el, SIR MACKENZIE (1823-). A Canadian statesman. He was born in England, but removed to Canada in 1833, received a common-school education, and became editor and proprietor of the Belleville *Intelligencer*. He served in the Dominion Parliament from 1867 to 1892, as a member of the Privy Council, and as Minister of Customs. He became Minister of Militia and Defense in 1892,

and from 1894 to 1896 was Premier. Later he was leader of the Conservative Opposition in the Senate (1896-1906). He was the representative of the Senate at King George's coronation in 1911.

BOWEN, bō'en, FRANCIS (1811-90). An American author, born in Charlestown, Mass. He graduated at Harvard in 1833, and became instructor there in intellectual philosophy and political economy. He was proprietor and editor of the *North American Review* from 1843 to 1854. His reactionary political views prevented his appointment in 1850, but three years later he was appointed to the Alford professorship of natural religion, moral philosophy, and civil polity at Harvard. In philosophy and metaphysics he opposed the views of Cousin, Comte, Fichte, Kant, and Mill, and upheld those of Locke and Berkeley. Among his publications are: *Lectures on the "Application of Metaphysical and Ethical Science to the Evidences of Religion"* (1849); *Lectures on Political Economy* (1850); *Critical Essays on the History and Present Condition of Speculative Philosophy* (1842); *Documents of the Constitution of England and America, from Magna Charta to the Federal Constitution of 1789* (1854); *Principles of Political Economy* (1856); *Gleanings from a Literary Life, 1838-80* (1880); *A Layman's Study of the English Bible* (1886).

BOWEN, SM GEORGE FERGUSON (1821-99). An English administrator. He was born in Ireland and was educated at Oxford. He served for a time as president of the University of Corfu and afterward became chief secretary of government in the Ionian Islands (1854); first Governor of Queensland (1859), and Governor of New Zealand (1868), where he had the difficult task of bringing the Maori War to an end. He was Governor of Victoria from 1872 to 1879, of Mauritius from 1879 to 1883, and of Hongkong from 1883 to 1887, when he retired on a pension. In 1888, however, he was royal commissioner at Malta to report on arrangements for the new constitution granted that island. He wrote: *Ithaca in 1850*; *Murray's Handbook for Greece* (1854; 6th ed., London, 1896); *Mount Athos, Thessaly, and Epirus* (1852); *Thirty Years of Colonial Government* (1889), a collection of his dispatches and letters.

BOWEN, HENRY CHANDLER (1813-96). An American publisher, born in Woodstock, Conn. He received an academic education, came to New York in 1833, and established the firm of Bowen & McNamee, dry-goods and silk merchants. In 1843 he assisted in founding the *New York Independent*, of which he became publisher, proprietor, and editor. In 1852 his firm was boycotted in the South on account of his public denunciation of the Fugitive Slave Law and became famous for the statement that the firm had "its goods but not its principles for sale." He was long known for his annual "gatherings" at Woodstock, where very distinguished statesmen, authors, and others were entertained.

BOWEN, HERBERT WOLCOTT (1856-). An American diplomat and writer, born in Brooklyn, N. Y., and educated at the Brooklyn Polytechnic Institute, in Europe, at Yale, and at Columbia Law School. He engaged in the practice of his profession in New York City. For 15 years he was a representative of the United States abroad, first as Consul and Consul General at Barcelona, Spain, then as Minis-

ter and Consul General at Teheran, Persia, and, finally, as Minister to Venezuela. In this difficult position he remained from 1901 until 1905, when, as the result of criticism as to his conduct of affairs, he resigned and retired from the diplomatic service. He published *Verses* (1894), *Losing Ground* (1889), *In Divers Tones* (1890), *De Genere Humano* (1893), *International Law* (1895).

BOWEN, JOHN WESLEY EDWARD (1855-) An American theologian, born in New Orleans. He graduated at the universities of New Orleans and Boston, and was professor of ancient languages at Central Tennessee College (1878-82), professor of church history and systematic theology at Morgan College, Baltimore (1888-91), professor of Hebrew at Howard University, Washington (1891-92). In 1893 he became professor of the history of theology in the Gammon Theological Seminary, South Atlanta, Ga., and was later made president. He also held several pastorates and was secretary of various church organizations. His writings include *Africa and the American Negro*, *The Catholic Spirit of Methodism*, *The Theology and Psychology of the Negro Plantation Melodies*, *An Apology for the Higher Education of the Negro*, *The United Negro* (1902).

BOWENITE, bö'en-it. A massive variety of serpentine, of an apple-green or greenish-white color, that is found in Smithfield, R. I., and in other serpentine localities. It was named after George T. Bowen, who described it in 1882.

BOWER, bou'ér, ARCHIBALD (1686-1766). A Scottish ecclesiastical historian. He was born in Dundee, was educated at the Scotch College in Douai, and in 1706 was admitted to the Jesuit order. He studied divinity in Rome and Arezzo and from 1723 to 1726 was a member of the Court of the Inquisition in Macerata. In the latter year he returned to England and entered the Established church. In 1745 he was readmitted to the Jesuit order, but in 1747 professed again to have left the Church of Rome. He was severely attacked for his changes of religion and for the alleged lack of originality displayed in his *History of the Popes* (1748-66), his best-known work, and the most complete of the sort in the language. It was reprinted in Philadelphia in 1844-46, with a continuation in 3 vols. by Dr. S. H. Cox.

BOWER, FREDERICK ORPEN (1855-) An English botanist. He was born at Ripon, Yorkshire, and was educated at Trinity College, Cambridge. In 1882 he was appointed first lecturer in botany in the Normal School of Science (now Royal College of Science), and in 1885 he became regius professor of botany in the University of Glasgow. During the following four years he also acted as examiner in the University of London. His works include *A Course of Practical Instruction in Botany*, in collaboration with Professor Vines (1891), *Practical Botany for Beginners* (1894), a translation, prepared in collaboration with Dr. D. H. Scott, of the *Comparative Anatomy of Phanerogams and Ferns* by De Bary (1884), *The Origin of a Land Flora* (1908), *Plant Life on Land* (1911). His most important contributions are a series of monographs entitled *Studies in the Morphology of Spore-Producing Members*, and another series, still current, entitled *Studies in the Phylogeny of the Finales*. As indicated by these monographs, the Pteridophytes are the special subject of his investigations.

BOWER, or BOWMAKER, WALTER (1385-1449). An abbot of the monastery of St. Columba, island of Inchcolm, Firth of Forth, and one of the authors of the *Scotichronicon*. He began about 1440 his continuation of John Fordun's *Chronica Gentis Scotorum*. The work was originally divided into 16 books, of which the first five and a part of the sixth were largely by Fordun. Bower added material in the first five books and carried the account on to the death of James I (1437). The *Scotichronicon*, completed in 1447, he subsequently abridged into the manuscript now contained in the Advocates' Library of Edinburgh and known as *The Book of Cupar*. There is an edition of the *Scotichronicon*, prepared by Walter Goodall from the Edinburgh College Library manuscript and published at Edinburgh in 1759. Consult Tytler, *Lives of Scottish Worthies*, vol. 11 (London, 1845).

BOWERBANK, bou'ér-bānk, JAMES SCOTT (1797-1877). An English geologist, born in Bishopsgate, London. In 1836 he associated himself with six friends in originating "The London Clay Club" for the examination of fossils of the Tertiary formation and the preparation of a list of the species found in it. In 1840 he published a volume on the *Fossil Fruits of the London Clay*, which is still regarded as a standard work. In 1847 he was an associate founder of the Palaeontographical Society. On his retirement from active life he devoted himself to the completion of his great work on sponges, to which subject he had for many years devoted considerable study. He was an indefatigable collector, and in 1864 his collection was bought by the British Museum, of which it now forms a well-known and important division. In addition to numerous scientific papers published by him in the *Journal of the Microscopic Society*, the *Journal of the Geological Society*, etc., he is the author of the interesting contributions entitled "The Pterodactyles of the Chalk," in *Proceedings of the Zoological Society*, and of contributions to a *General History of the Spongiae*. His most important work, *A Monograph of the British Spongiae*, appeared in 4 vols., 1864-82, under the auspices of the Ray Society.

BOWER BIRD. One of certain Australasian birds remarkable for making ornamented bower-like structures, locally known as "runs," as places of resort, especially in the breeding season. They were formerly considered as members of the family of the birds of paradise, but now the numerous genera and species are placed in the family Ptilonorhynchidae. There are 14 genera embracing about 37 species. All are of moderate size and plain plumage, subsist mainly upon fruits, and breed in trees, constructing rather rude nests for their eggs, for their terrestrial bowers are not nesting places, but "playhouses." These birds were first described in 1840 by Dr. John Gould, the ornithological explorer of Australia, but much new information has since been gained. Several species are usually living and working in the Zoological Gardens in London and elsewhere.

The most familiar species is the satin bower bird (*Ptilonorhynchus holosericeus*, or *volaceus*), found over a great part of southern and eastern Australia, from Port Phillip, in Victoria, to Moreton Bay, in Queensland. It is about the size and somewhat the shape of a jackdaw, but the sexes are dissimilar, the males

BOWER BIRDS

1. BOWER OF SATIN BOWER BIRD (*Ptilonorhynchus holosericeus*).

2. HUT AND GARDEN OF THE GARDENER BOWER BIRD (*Amblyornis inornatus*).

having a plumage of satiny black, while the females and young are grayish green. In manners they exhibit great alertness and an almost irrepressible activity. "In their native wilds," writes an observer to *The Field*, of London, "the site chosen for the playground is some open spot in the most retired parts of the New South Wales forests. There, in the neighborhood of berry-bearing plants, and scrubs studded with enormous fig trees (to the fruit of which they are especially partial), having cleared the turf of all inharmonious objects and dead leaves, the male constructs a dome-shaped gallery, open at either end, and about a foot long, with the floor and sides formed of sticks and twigs. Those used for the latter are longer and more slender, and so arranged that they lean inward, nearly meeting overhead. The floor, or platform, in which the sides are firmly planted, is sometimes ornamented with a few feathers, but around the entrance are scattered every variety of decorative material, such as brightly-colored feathers, bones, and shells, which are often brought from long distances in the bush for this purpose; and scarcely a day passes without the birds making some fresh arrangement or adding to their store of curios. Like too many of their crow-like relatives, they pay little regard to the Eighth Commandment; and Mr. Gould says that the natives are in the habit of searching their arbors for anything that has been lost or dropped in the bush, and frequently recover missing articles in this way. When this summerhouse is complete, little 'at homes' are given daily, at which the males meet and pay their court to the females, and, with ruffled feathers and many bows and scrapes, go through the most absurd, not to say stately, dance, for the edification of their ladyloves, or at other times pursue them through the gallery with the utmost glee in a wild game of 'hide and seek.' The captives in zoölogical gardens seem never at rest, and when not feeding or flirting are constantly engaged in flying backward and forward through their aviary. The male never appears content with his architecture, and amuses himself by constantly pulling down his summer palace and rebuilding it in improved style."

The regent bird (*Sericulus chrysocephalus*, or *melinus*), which has a rather limited range in the region north of Sydney, and breeds along Brisbane River, is a near relative, but the fully plumaged males have rich yellow markings on the head, neck, and wings; and it builds a bower resembling that of the satin bower bird, but decorated exclusively with snail shells. It is so pugnacious that the males often kill one another in their fights at the nuptial season. Allied Queensland species of the genera *Scopætes* and *Alcedius* are not known to build bowers, but clear wide spaces of ground on which to display themselves, and ornament them with leaves, renewed as fast as they decay. To the latter genus belong the "catbirds" of southern Australia.

The spotted bower birds of the genus *Chalmydodera* form still more elaborate runs. There are several species, all characterized by the pink, collar-like marking on the necks of the males, which inhabit bushy districts in southern Australia and northern New Guinea. Their structures take the form of avenues about 3 feet long and 8 inches broad inside; the walls of upright twigs, rising from a dense platform, bend in at the top, but do not meet. This avenue and the

ground near it are always strewn with hundreds of white pebbles, shells, bleached bones, and other bright objects, which the birds delight to gather, arrange, and rearrange.

Of a different and even more remarkable character are the structures of the related gardener bird (*Amblyornis inornatus*) of New Guinea, first described by the Italian naturalist Dr. O. Beccari, in the *Annals of the Museum of Genoa* (vol. ix, p. 382, Pl. 8). Choosing a level spot in the forest, this bird clears a space around a sapling the size of a walking stick and heaps up around its base a cone of mosses about 18 inches in height. Around this is built a conical hut, made by leaning from the ground to the central pillar, at a little distance above the interior cone, thin, straw-like stems of an epiphytal orchid, which serve as rafters; these are interwoven and well thatched with others of the same sort, forming a "wigwam" open in front, but covering a gallery running around the pillar. The orchids of which it is composed retain their leaves and remain alive and blooming for a long while; and Dr. Beccari believes that they are chosen by the birds on this account. "But," he says, "the æsthetic tastes of our 'gardener' are not restricted to the construction of a cabin. Their fondness for flowers and for gardens is still more remarkable. Directly in front of the entrance to their cabin . . . is a miniature meadow of soft moss, transported thither, kept smooth and clean and free from grass, weeds, stones, and other objects not in harmony with its design. Upon this graceful green carpet are scattered flowers and fruit of different colors in such a manner that they really present the appearance of an elegant little garden. . . . Showy fungi and elegantly colored insects are also distributed about the garden and within the galleries of the cabin. When these objects have been exposed so long as to lose their freshness, they are taken from the abode, thrown away, and replaced by others." Each of these huts and its garden are believed to be the work of a single pair, or perhaps of the male alone; and they seem to be utilized year after year.

Not less remarkable is the bower of birds of the genus *Prionodura*, described by Mr. Devis in the *Transactions of the Royal Society of Queensland* for 1889 as a collection of huts looking not unlike a dwarfed camp of the aborigines.

The purpose of these structures is perhaps best characterized by the term "playhouse," and they are merely the carrying out architecturally of the same feeling which leads many other birds to resort to certain spots, and in some cases to prepare them, by scratching or other simple efforts, for the purpose of playing with one another, or of going through the dancing and antics that are a part of the method of courtship. This phase of bird life has been treated more or less by all writers upon birds, and especially for those of the North Atlantic shores by Edmund Selous in *Bird Watching* (London, 1901); but the briefest general array of such facts is contained in chap. xii of Darwin's *Descent of Man*. Many birds show a distinct preference for bright objects about them and adorn their nests for no other apparent reason than æsthetic enjoyment; and the fondness shown by the bower birds for pretty ornaments seems only the highest development of this wide tendency. They replace dying leaves and faded flowers with fresh ones, and move about and arrange their shells and pebbles precisely as if it were an amusement

and mental gratification to "play" with them and with each other in a nicely prepared place

BOWERS, bou'érz, ELIZABETH CROCKER (1830-95) An American actress. She was born at Stamford, Conn., and first appeared on the stage in 1846, at the Park Theatre, New York. The next year she was married to David P. Bowers, an actor, with whom she went to Philadelphia and remained there till his death in 1857, playing at the Walnut Street and Arch Street theatres. In 1861, after her marriage to Dr. Brown, of Baltimore, she went to London and made a great success as Julia in *The Hunchback*, and as Geraldine D'Arcy in *Woman*. Returning to New York in 1863, she played for a time at the Winter Garden. Among her favorite parts were Juliet, Lady Macbeth, Marie Antoinette, and Lady Audley. After the death of Dr. Brown (in 1867) she married J. C. McCollom, with whom she repeated many of her popular rôles. Her subsequent retirement at Philadelphia was interrupted by a return to the stage, in 1886, for several years. Under A. M. Palmer's management she appeared in *Lady Windermere's Fan* (1893), and later she supported Rose Coghlan and Olga Nethersole. Her death occurred in Philadelphia, where she made her home.

BOWERS, LLOYD WHEATON (1859-1910) An American lawyer of distinction. He was born in Springfield, Mass., graduated from Yale University in 1879 and from the Columbia Law School in 1882, in which year he was admitted to the bar. Removing to Winona, Minn., a few years later, he quickly attained distinction at the bar and in 1887 became general counsel of the Chicago and Northwestern Railway Company. Here his penetrating and well-informed mind, and his remarkable grasp of the relations of the great public-service corporations to the public interest, enabled him to render important service in the adjustment of those relations. In March, 1909, by appointment of President Taft, he became Solicitor-General of the United States, an office which he filled with unrivaled success. He left no published works.

BOWERS, THEODORE S. (1832-66) An American soldier, born in Pennsylvania. He entered the army in 1861, was appointed aid-de-camp to General Grant, and after the surrender of Vicksburg became assistant adjutant general of volunteers, serving in the field and at Washington, on General Grant's staff. He was killed by an accident in 1866. For gallant service he was brevetted lieutenant colonel, colonel, and brigadier general, U. S. A.

BOWERLY, THE (Dutch *bouwewry*, farming, farm, from *bouwer*, farmer, Ger. *Bauer*, rustic, peasant, Eng. *boor*). A broad avenue in New York City, parallel with Broadway, extending from Chatham Square to the junction of Third and Fourth avenues at Cooper Union. Its original name, the *Bouwerie*, was derived from the estates of the Governor, Peter Stuyvesant, whose farm and orchards, embracing the region lying about the upper part, were called the Great Bouwerie. Once notorious as the rendezvous of the lawless "Bowery Boy," the street at the present time has changed for the better and is characterized by heterogeneity of population and a multitude of cheap shops.

BOWFIN, bö'fin' A peculiar fish of the Mississippi valley and Great Lakes, representing an order (Cyclogonoidea or Halecomorphi) and a family (Amidae), having affinities with both ganoid and isospondylous fishes. Only a single

living species remains—the bowfin or mudfish (*Amia calva*), of sluggish streams throughout the central United States, from Lake Superior to Florida and Texas, but the group is largely represented by fossil forms, and, according to Jordan, "it is probable that the ancestors of the Isospondyli [shad, salmon, and their relatives] are to be found among forms allied to the existing Halecomorphi." The bowfin attains a length of about 2 feet and a weight of 12 pounds, and, unlike its allies, the garfishes, is covered with hard, rounded scales, the fore part of the body is cylindrical, the head stout and blunt, and the mouth filled with powerful teeth. It is exceedingly hardy, enduring absence from the water for a long time, as well as grievous injury, hence the young are the favorite live bait of anglers in the Mississippi valley, and make interesting captives in an aquarium, where, however, nothing else but snails can remain alive. These fish are strong, active, voracious, and gamy, taking a trolling spoon with avidity and resisting capture strongly. They feed upon all sorts of small aquatic creatures. They spawn late in spring, in warm shallows, among waterweeds, where the guarded eggs hatch in 8 or 10 days, after which the young remain with the parents for two or three weeks, during which time they are said to retreat into their parent's mouth for protection when danger threatens them. They do not venture into open lakes or deep water until the following season. The flesh is considered hardly eatable in the Northern States, but is a favorite with the negroes of the South. Other Northern names for this fish are dogfish and lawyer, and in the South it is known as mudfish and grindle, or John A. Grindle. Consult Hallock, *Sportsman's Gazetteer* (New York, 1877), and Goode, *Fishery Industries, Section I* (Washington, 1884). See Plate of STURGEONS, PADDLEFISH, AND BOWFIN.

BOWHEAD, bö'héd' A whalebone whale, especially the great Greenland species, in reference to the arched outline of its head. See WHALE.

BOWIE, bö'wī or bö'ī A city in Montague Co., Tex., 68 miles north of Fort Worth, on the Fort Worth and Denver and the Chicago, Rock Island, and Gulf railroads (Map Texas, D 3). It is in a rich agricultural region, producing cotton, grain, and live stock, and has oil compresses, cotton gins, and cold storage plant. The water works are owned by the municipality. Pop., 1890, 1486, 1900, 2600, 1910, 2874.

BOWIE (bö'e) KNIFE A large hunting knife often carried by pioneers of the Southwest and improved by Col. James Bowie, whose name it bears.

BOWKER, bou'kér, RICHARD ROGERS (1848-) An American editor and writer. He was born in Salem, Mass., and graduated at the College of the City of New York in 1868. He became literary editor of the New York *Evening Mail* in 1869. He was a leader in the Independent Republican or "Mugwump" movement in 1879. His publications include *Work and Wealth*, *Economos for the People*, *Copyright Its History and its Law* (1912). He also edited the *Annual Literary Index* (1892-1904), and the *Annual American Catalogue* (1886-1906).

BOWLER. See BOULDER, ERRATIC.

BOW LEG. See LEG.

BOWLES, CAROLINE. See SOUTHEY.

BOWLES, bölz, FRANCIS TIFFANT (1858-) An American naval constructor. He was

born in Springfield, Mass., graduated in 1879 at the United States Naval Academy, studied at the Royal Naval College, Greenwich, England, and was appointed to the United States naval advisory board in 1882. He was long director of repairs and construction in the Norfolk (Va.) and Brooklyn (N. Y.) navy yards, and became chief constructor of the United States navy. In 1901 he was made a rear admiral. He resigned in 1903 and became president of the Fore River Shipbuilding Company.

BOWLES, SAMUEL (1826-78). An American journalist, born in Massachusetts. For more than 30 years he was editor of the *Springfield* (Mass.) *Republican*, which had been established by his father, the elder Samuel Bowles, and which soon became one of the leading journals in New England. He traveled widely over the United States and was always warmly interested in political affairs, though never holding office. As a practical editor, Bowles stood almost in the first rank, satisfied with nothing less than the best work, sparing neither his own nor his subordinates' strength, nor hampered in his work by either fear or friendship. The *Republican* under his direction was involved in the slavery controversies as a Whig, and then as a Republican newspaper. Later it joined Horace Greeley in the Liberal Republican movement, and finally it became independent. Its vigorous, incisive editorials were the first to advocate free suffrage for both white and black, and one of the first to take up the cause of woman suffrage. Mr. Bowles's travels gave rise to the volume *Our New West* (1869), which, with his numerous editorial writings, showed him a master of clear and vigorous English. Consult G. S. Merriam, *The Life and Times of Samuel Bowles* (New York, 1885).

BOWLES, WILLIAM LISLE (1762-1850). An English poet. He was born Sept. 24, 1762, at King's Sutton, Northamptonshire, where his father was then vicar. He received his education at Winchester School, and at Trinity College, Oxford. In 1804 he became vicar of Bremhill, Wiltshire, and a prebendary of Salisbury Cathedral. Here he spent the remainder of his long life. He died at the Close, Salisbury, April 7, 1850. His poetical career began with the publication, in 1789, of *Fourteen Sonnets, Written Chiefly on Picturesque Spots during a Journey*. This unpretending volume was received with extraordinary favor; the sonnets were fresh and natural, and to many minds all the more charming because of the contrast which they presented to the style of poetry which had long been prevalent. Coleridge, Wordsworth, and Southey were among their enthusiastic admirers; and through the influence which he exercised over them, Bowles may be regarded as the founder of a school of English poetry, in which other names soon became greater than his own, but Hazlitt (q.v.) gave critical credit to Bowles. The subsequent poetical works of Bowles are very numerous, of which "The Spirit of Discovery" and "The Missionary" are generally regarded as the best of his longer blank-verse poems. Bowles was also an antiquarian of repute; and as a literary critic he was the cause of a memorable controversy on the question whether Pope was a poet. Consult Gilfillan, *Poetical Works*, with memoir (ed. Edinburgh, 1855).

BOWLINE, bô'lin (bow of a ship + line). 1. A rope fastened near the middle of the perpendicular edges of the square sails by three or

four subordinate ropes called *bridles*. It is employed to tighten the edge of the sail and make it lie flatter when sailing close to the wind. 2. A knot. See Plate of KNOTTING AND SPLICING.

BOWLING. Bowling on alleys seems to have been derived from the old game of skittles (q.v.), which, in turn, probably developed from the still older game of bowls (q.v.). It has its greatest vogue in the United States, where its popularity has increased very rapidly, especially since the latter part of the last century. The first record of a game in America was on Jan. 1, 1840, in New York City. The game grew slowly from that time until 1875, when the National Bowling League was formed. The rules were few, and the conditions of matches varied with each match until 1895, when the American Bowling Congress was formed and made rules which, with few modifications, have been used ever since. The alleys may not be less than 41 or more than 42 inches wide, and the length from the centre of pin No. 1, which is the head of a triangle of 10 pins, to the foul line behind which the bowler must deliver the ball must be 60 feet. The pin spots must be clearly marked or imbedded in the alleys and placed 12 inches apart from centre to centre. They must be $2\frac{1}{4}$ inches in diameter, the size of the bottom of the pin. The four rear pins must be placed 3 inches from the centre of the pin to the edge of the pit at the end of the alley. The pins must be 15 inches high, and their largest circumference must be 11½ inches, with a minimum weight of 3 pounds, 2 ounces. Balls may not be more than 27 inches in circumference or 16½ pounds in weight.

The aim is to bowl down all the pins in the two balls or frame which each player rolls in turn. Should the player knock down all the pins with the first ball he is credited with a *strike*, and may add to the 10 thus scored the number of points made on the next two balls that he may roll. If the pins all fall in two rolled balls, the player scores a *spare*, and to the 10 thus scored may add the points gained in the next ball he may roll. When a player makes a large number of strikes and spares in a game, the scoring becomes somewhat complex, and a large total is quickly gained. Ten frames for each player constitute a game. The variations are cocked hat, cocked hat and feather, college game, Newport game, headpin game, Glen Island, seven up, ninepins headpin out, T game, pin pool, nine up and nine down, four back, five back, white elephant, open game, seven down, and others. The American Bowling Congress has annual championship meetings in various parts of the United States, titles being awarded for four-men teams, two-men teams and individuals. Some of the world's records (in 1912) are as follows: high individual score, 280, A. B. C. tournament, 1912; high individual total for three games, 771, Canadian B. A. tournament, 1912; high two-men, single game, 523, Nat. B. A. tournament, 1908; individual, open three games, 869, average 289½, at Wilmington, Del., 1908, six games, 1628, average 271½, at Newark, N. J., 1909; three games, tournament, 824, average, 271½, at Brooklyn, N. Y., 1907. Consult Karpf, "Bowling," *Spalding's Athletic Library* (New York, annually).

BOWLING, bô'ling, TOM. 1. The name of a sailor in Smollett's *Roderick Random*. 2. The same, in a song of that title by Charles Dibdin.

BOWLING GREEN. A city and the county

seat of Warren Co., Ky., 114 miles southwest of Louisville, on the Barren River, at the head of navigation, and on the Louisville and Nashville Railroad (Map Kentucky, D 5). It is in a fertile agricultural region producing corn, hay, wheat, oats, vegetables and tobacco, and has an important trade in mules, cattle, and hogs, and its horse market is one of the largest in Kentucky. There is also a handle factory. The city has two parks, the larger of 42 acres, interesting from an historical standpoint, and contains Ogden College (non-sectarian), opened in 1877, Western Kentucky Normal School, Bowling Green Business University, and Saint Columba's Academy. Bowling Green was first incorporated in 1812, and is now governed under a charter of 1893, which provides for a mayor, elected every four years, and a city council elected on a general ticket. The water works and street electric light plant are owned and operated by the municipality. During the Civil War the place was regarded by the Confederates as of considerable strategic importance. Pop., 1890, 7803, 1900, 8226, 1910, 9178.

BOWLING GREEN. A city and the county seat of Pike Co., Mo., 90 miles northwest of St. Louis, on the Chicago and Alton and the St. Louis and Hannibal railroads (Map Missouri, E 2). It has a private academy (Pike College) and a sanatorium. The leading industrial establishments are a flour mill and a pipe factory, and there are extensive stone quarries in the vicinity. Settled in 1820, Bowling Green was incorporated in 1838. Its present government is administered under general statutes for cities of the fourth class, which provide for a mayor, elected biennially, and a board of aldermen. Pop., 1900, 1902, 1010, 1585.

BOWLING GREEN. A city and the county seat of Wood Co., Ohio, 22 miles south of Toledo, on the Cincinnati, Hamilton, and Dayton, and the Toledo and Ohio Central railroads (Map Ohio, C 3). Among the more notable features of the city are the courthouse, high school, State Normal College, and city hall buildings. It is in an agricultural district and carries on a trade in grain and general farm produce, and is the centre of a great oil and natural-gas region. There are also foundries, and manufactories of motor trucks, machinery, marine engines, and underwear. The city has a hot-water heating plant. Settled in 1832, Bowling Green was incorporated in 1854. The government, under the revised charter of 1901, is vested in a mayor, elected biennially, and a council. Pop., 1900, 5067, 1910, 5222.

BOWLING GREEN. A triangular strip of land at the foot of Broadway, New York, containing a small oval park. Early in the Dutch occupancy of New York the place was laid out as a village green and parade ground. Facing it on the south stood Fort Amsterdam, built in 1626 and torn down in 1787, when a mansion was erected on its site for Washington, who, however, did not occupy it, and it became the official residence of Governors Clinton and Jay. The Governor's mansion in turn gave way to a row of fine brick residences, the famous "Mushroom Row," in recent years occupied by steamship offices, and torn down in 1901 to make room for the new customhouse. In Colonial times the Bowling Green was surrounded by aristocratic dwellings, the site of which is now occupied by lofty office buildings. In 1770 the citizens erected on the Green an equestrian statue of George

III, which was pulled down after the reading of the Declaration of Independence on July 9, 1776, and converted into 48,000 leaden bullets for use against the English.

BOWLS, *bôlz* (Fr. *boule*, It. *bolla*, *bullo*, from Lat. *bullo*, bubble, a round object). Excepting archery, this is the oldest British outdoor sport still practiced. It was played in England as early as the thirteenth century (perhaps during the twelfth) and was brought to America apparently by the English. A resolution of the Corporation of New York, in 1732, authorized the establishment of a "Bowling Green" for the recreation and delight of the inhabitants of the city, within the tract at the southern end of the island theretofore known as "The Plane" or "The Parade." Three citizens leased the land for this purpose (at a rental of one peppercorn per annum), and prepared a strip of it for the game of bowls. This was the origin of the present name "Bowling Green," one of the very oldest geographic designations still in use in New York City. The Revolutionary War put an end to the sport in New York, and it seems to have been played very little thereafter in America until it was again introduced, in 1879, by Christian Schepflin, of Dunellen, N. J., who had seen it played in England. Within a few years clubs had been formed in many cities throughout the United States, where it is sometimes called "lawn bowls."

The *Green* should be not less than 40 yards square, as nearly level as possible, very closely cropped and surrounded by a ditch 6 inches deep and a foot wide, flanked by a terrace 2 feet high. It is divided into four "rinks," each from 19 to 21 feet wide. The *Bowl*, which is of lignum-vitæ, made with one side slightly more convex than the other, must not exceed 16½ inches in circumference nor 3½ pounds in weight. The *Jack*, a white porcelain ball about 2½ inches in diameter, is the object played for. The *Mat*, usually 22 inches long by 14 inches wide, is made of corrugated or perforated rubber, and the player must have at least one foot on it when playing. The object of the game is to place the bowl against or as near as possible to the jack. In the four-handed game the players in each rink (or team) are termed "Lead," "Second," "Third," and "Skip," the last-named being always the captain and directing the play of his team.

The Scottish form of the game provides for a contest of 32 points, 8 at each of four kinds of play, styled "drawing," "guarding," "trailing," and "driving." The game is also played (chiefly in the northern and middle counties of England) on a "crown green," which may have a maximum fall of 18 inches from the centre to the edges.

Consult Grieg, "The Game of Bowling on the Green, or Lawn Bowls," Spalding's *Athletic Library* (New York, annually), also, Elliott, "Bowling on the Green," *Canadian Magazine*, vol. xix (Toronto, 1902), Macgregor, "The Game of Bowls"—early history of the game—*Belgravia*, vol. xxxvi (London, 1878), Stephantot, "Bowling Greens"—early history—*The Antiquary*, vol. xiv (London, 1886), Manson, *The Complete Bowler* (London, 1912).

BOWMAKER, WALTER. See BOWER, WALTER. **BOWMAN,** bô'man, ALEXANDER HAMILTON (1803-65). An American soldier. He was born in Wilkesbarre, Pa., and in 1825 graduated at

West Point, where he taught for one year as assistant professor of geography, history, and ethics. He then became assistant engineer in the construction of defensive works and of harbor improvements on the Gulf of Mexico. From 1834 to 1839 he was engaged in constructing the Memphis and St. Francis military road and in improving the navigation of the Cumberland and Tennessee rivers. He was instructor of practical military engineering at West Point (1851-52) and in 1853 was appointed chief engineer of the construction bureau of the United States Treasury Department. During the Civil War he was superintendent of the United States Military Academy, with the local rank of colonel.

BOWMAN, EDWARD MORRIS (1848-1913). An American organist, pianist, choral conductor, and teacher; born in Barnard, Vt. He studied under Dr. William Mason and John P. Morgan, of New York; Weitzmann, Rohde, August Haupt, and Franz Bendel, of Berlin; Batiste and Guilman, of Paris, and Drs. MacFarren, Bridge, and E. H. Turpin, of London. In 1877 he published the *Bowman-Weitzmann Manual of Musical Theory*, a compilation from his student notes of Weitzmann's theory of harmony. This valuable textbook, indorsed by Weitzmann, was subsequently translated into German. In 1881, while in London, he passed the examination of the Royal College of Organists and became the first American associate. Beginning in 1884, he served eight terms as president of the American College of Musicians, of which he was the projector and one of the founders, and of which he afterward became honorary president and trustee. In 1895 he became organist and conductor of the Temple Choir, in connection with the Baptist Temple, in Brooklyn, N. Y., which, while popularizing, has contributed greatly to raise the standard of music, both ecclesiastical and secular, in that metropolitan borough. Mr. Bowman's compositions include songs, part songs, anthems, and orchestral numbers. One of the leading concert organists and pianists in the United States, he was also one of its most successful theorists, lecturers, and teachers. In 1891 he succeeded Dr. F. L. Ritter as professor of music in Vassar College, and in 1892 was also appointed examiner to Evelyn College, Princeton, N. J. From 1906 until his death he was musical director of Calvary Baptist Church in New York. His published lectures include: *Harmony: Historic Points and Modern Methods*; *Formation of Piano Touch*; *Relation of Musicians to the Public*.

BOWMAN, ISALAH (1878-). An American geographer, born at Waterloo, Canada. He was educated at Harvard and Yale universities and was instructor in geography at the State Normal College, Ypsilanti, Mich., in 1902-03, assistant in physiography at Harvard in 1904-05, and instructor in geography at Yale in 1905-09. In 1909 he became assistant professor at that institution and in 1907 was also leader of the Yale South American Expedition. His publications include *Forest Physiography* (1911) and *Well-Drilling Methods* (1911).

BOWMAN, THOMAS (1817-1914). An American clergyman, born in Columbia Co., Pa. He graduated at Dickinson College in 1837, studied law at Carlisle for a year, and in 1839 became a minister in the Methodist Episcopal church. He taught in the grammar school of Dickinson College from 1840 to 1843, and from 1848 to 1858 was president of the Dickinson Seminary at Williamsport, Pa., which he himself had

founded. In 1858 he was chosen president of Asbury University (now De Pauw) at Greencastle, Ind. He was chaplain to the United States Senate in 1864 and 1865. In May, 1872, he was chosen a bishop, and in 1878 he made an official visit to the Methodist missions in Europe and India. He became chancellor emeritus of De Pauw University in 1899.

BOWMAN, SIR WILLIAM (1816-92). An English ophthalmic surgeon, born at Nantwich. He studied at the General Hospital, Birmingham, at King's College, London, and on the Continent, and became a member of the Royal College of Surgeons in 1839. In 1840 he was appointed junior demonstrator of anatomy at King's College; in the same year assistant surgeon, and in 1856 full surgeon, in King's College Hospital; in 1846 assistant surgeon, and in 1851 full surgeon, in the Royal Ophthalmic Hospital, Moorfields. He was in 1843 elected to the chair of physiology and of general and morbid anatomy at King's College; in 1841 became a fellow of the Royal Society, and in 1844 of the Royal College of Surgeons. In 1880-83 he was the first president of the Ophthalmological Society of the United Kingdom. His *Lectures on the Eye* (1849) established his reputation. His services to general anatomy also were great. The results of many of his investigations in this field are to be found in papers read before the Royal Society, and in the *Anatomy and Physiology of Man*, with Todd (1843-56). His *Collected Papers* were published in 1892, edited by J. B. Sanderson and J. W. Hulke, with a memoir by H. Power.

BOWMAN'S ROOT. See GILLENIA.

BOWMANVILLE, bō'man-vil. A town in Durham Co., Ontario, Canada, on Lake Ontario and the Canadian Northern and Grand Trunk railroads, 42 miles northeast of Toronto (Map: Ontario, F 6). It manufactures agricultural machinery, iron castings, linens and woollens, pianos and organs, rubber goods, bricks, fruit and vegetable evaporators, furniture, and flour. There is trade in apples, cheese, live stock, and grain, and considerable lake commerce. It is a port of entry, with a harbor at Port Bowmanville. Pop., 1901, 2731; 1911, 2814.

BOWNE, bound, or **BOUND**, NICHOLAS (?-1613). An English clergyman. A son of Richard Bownde, physician to the Duke of Norfolk. He was educated at Cambridge and Oxford. He became famous through his treatise on the Sabbath (1st ed. 1595), in which he contended that all manner of feasting, as well as May games, shooting, bowling, dances, and all other sports, were a profanation of the seventh day, which he held had been ordained as one of rest, similarly to the Jewish Sabbath. The so-called Sabbatarian Question, which thereby arose, constituted the first point of doctrinal difference between the High-Church party and the Puritans, and expressed the principal point of distinction between the two parties. In 1611 he was called to the pastorate of the church of St. Andrew the Apostle at Norwich, which position he held until his death. Among his published works are *The Doctrine of the Sabbath*, *Plainly Layde Forth* (1595); *The Holy Exercise of Fasting* (1604); and a *Table from the Beginning of the World to this Day, wherein is Declared in what Teere of the World Everything was Done* (1593).

BOWNE, boun, BORDEN PARKER (1847-1910). An American philosopher and educator, born at

Leonardville, N J He graduated at New York University in 1871, studied at Halle and Göttingen, and in 1876 was appointed professor of philosophy at Boston University His publications include *The Philosophy of Herbert Spencer* (1874), *Introduction to Psychological Theory* (1886), *Principles of Ethics* (1892), *The Christian Revelation* (1898), *The Christian Life* (1899), *The Immanence of God* (1905), *Kant and Spencer, a Critical Exposition* (1912)

BOWNOCKER, JOHN ADAMS (1865-). An American geologist, born at St. Paul, Ohio After graduating from Ohio State University he was principal of the high school at Martins Ferry, Ohio, in 1889-92, was assistant in 1892 on the Geological Survey of Ohio, and in 1893, on that of New Jersey, took up teaching at Ohio State University as assistant in 1895, and became assistant professor in 1898, associate professor of inorganic geology in 1899, and professor in 1901 In 1906 he was made State geologist of Ohio His publications include *The Oil- and Gas-Producing Rocks of Ohio* (1902) and *The Central Ohio Natural Gas Fields* (1903)

BOWRING, bow'ring, Sir JOHN (1792-1872) An English politician, linguist, and author He was born at Exeter, Oct 17, 1792 He early devoted himself to the study of languages, in the acquisition of which he displayed an unusual degree of talent The national poetry of different peoples had great attraction for him, and he rendered valuable service to literature by collecting and translating both the more ancient and the more modern popular poems of almost all the countries of Europe He edited the collected works of his friend, Jeremy Bentham He became the first editor of the *Westminster Review*, established in 1824 In 1828 he visited Holland, and his letters—which appeared in the *Morning Herald* and were afterward translated into Dutch—procured for him the degree of doctor of laws from the University of Groningen Subsequent travels were undertaken on a commission from the British government He visited Switzerland, Italy, Egypt, Syria, and finally the States of the German Zollverein, and everywhere found materials for valuable reports He was a member of the House of Commons from 1835 to 1837 and again from 1841 to 1849 and actively promoted the adoption of free trade In 1849 Bowring was appointed British consul at Hongkong, and superintendent of trade in China He returned in 1853, and in the following year was made knight, and subsequently Governor of Hongkong In 1856, an insult having been offered to a Chinese vessel, said to have been under the protection of the British flag, Bowring, without consulting the home government, ordered an attack on certain Chinese forts—a proceeding which excited considerable dissatisfaction in Great Britain In 1855 he concluded a commercial treaty with Siam and gave an interesting account of his visit in *The Kingdom and People of Siam* In 1858 he visited Manila and afterward published an account of the Philippine Islands He died Nov 23, 1872 Consult his *Autobiographical Reminiscences* (London, 1877), ed by Levin Bowring, Sir John's third son, who died in 1910

BOWSER, bow'zer, EDWARD ALBERT (1845-1910) An American mathematician, born at Sackville, New Brunswick He graduated at Rutgers College in 1868, was appointed pro-

fessor of mathematics there in 1870, and director of the United States Geodetic Survey of New Jersey in 1875 His publications include *Analytic Geometry* (1880), *Differential and Integral Calculus* (1880), *Analytic Mechanics* (1884), *Hydromechanics* (1885), *College Algebra* (1888), *Plane and Solid Geometry* (1890), *Treatise on Trigonometry* (1892), *Logarithmic Tables* (1895), *A Treatise on Roofs and Bridges* (1898)

BOWSPRIT, bō'sprit' (bow + sprit, OE *spret*, a spear) A large boom, spar, or mast projecting over the stem or head of a ship Its use is to carry sail forward, as a means of counteracting the effect of the after sails and keeping the ship well balanced It is also one of the chief supports of the foremast, which is fastened to it by large stays or ropes In ordinary ships, the bowsprit rises at an angle of about 30° from the horizon It is secured in place by heavy framing at the *heel* or inboard end—just inside the bow by iron straps or lashings of wire rope called the *gammoning*, which hold it down to the stem, and outside the ship by the *bobstays*, which extend from the bowsprit to the cutwater

BOWSTRING (bō'string') **HEMP** See **HEMP**, **BOWSTRING**

BOW WINDOW See **BAY WINDOW**

BOW-WOW **THEORY OF LANGUAGE** See **ONOMATOPEIA**

BOX, *Buxus* (Lat *buxus*, from Gk *βύτος*, *pyraos*) A genus of plants of the family Buxaceae, evergreen shrubs or small trees, with opposite leaves, entire at the margins, and with greenish, inconspicuous flowers in little axillary clusters, the male and female flowers distinct, but on the same plant The most important species is the common box (*Buxus sempervirens*), which grows wild in the south of Europe and in some parts of Asia, attaining a height of 20 or more feet, its leaves are oval, generally from half to three-quarters of an inch in length, smooth and shining, of a deep-green color and a compact habit of growth There are several cultivated varieties distinguished by differently variegated leaves—gold-edged, silver-edged, etc Dwarf box grows only to a height of two or three feet and is very commonly used to form borders for garden plots, being kept down by clipping to a height of a few inches The box bears clipping remarkably well and is much used in formal gardens for this purpose The wood of the box is heavy, of a beautiful, pale-yellow color, remarkably hard and strong, of a fine, regular, and compact texture, capable of a beautiful polish, and not liable to be worm-eaten It is much valued for the purpose of the turner and the wood carver, is preferred to every other kind of wood for the manufacture of flutes, flageolets, and other wind instruments, as well as of mathematical instruments, and is unrivaled for wood engraving (See **WOOD ENGRAVING**) Spain, Portugal, Circassia, and Georgia send into the market large quantities of boxwood The Minorca box, or Balearic box (*Buxus balearica*), a native of Minorca, Sardinia, Corsica, Turkey, etc., is a larger tree than the common box The wood is of a bright yellow and inferior to the true boxwood, but is exported in large quantities from Constantinople The earliest known fossil forms of *Buxus* have been found in the Pliocene deposits of France For illustration, see **BEECH**, and Plate of **BIGNONIA**

BOX AND COX. A short farce by John M. Morton. A landlady, Mrs. Bouncer, unknown to both, lets her single room to two men of these names, one of whom works in the daytime, the other at night.

BOX'BER'RY. See GAULTHERIA.

BOX ELDER (*box*, the tree + *elder* or *alder*), or **ASH-LEAVED MAPLE** (*Acer negundo*, or *Negundo aceroides*). One of the hardiest and most widely distributed trees in the United States, ranging from Vermont to Florida, and westward to Utah and Arizona. A form known as *Acer negundo californica* is found in California. In rich river bottoms it often attains a height of more than 60 feet and a diameter of 3 feet. The wood is light and soft and is suitable for woodenware, wood pulp, etc. The box elder is considered a good shade tree, and it has been extensively employed in plantings in the Western States for windbreaks, shade, fuel, etc. It grows rapidly and serves as an excellent nurse tree for other species. In some parts of the Northwestern States sugar is made from the sap. See Plate of BIGNONIA.

BOX'ERS' REBEL'ION. See CHINA.

BOX'FISH. See TRUNKFISH; SWELL.

BOX'HAUL'ING. A method of changing a ship from one tack to the other. It is resorted to when a ship fails to go around (i.e., *misses stays*) while attempting to tack in narrow waters, or on a lee shore, and there is no room to *wear*, and in narrow channels when there is danger of running on shore in tacking. The first part of the manoeuvre resembles tacking; the helm (q.v.) is put down and the ship brought up head to wind with all the sails aback. Her headway is thus quickly checked, the head yards (those on the foremast) are then swung around (i.e., braced *abow*, from which circumstance the manoeuvre takes its name), as if on the other tack, and the after yards (those on the mainmast and mizzenmast) *squared* (i.e., placed athwartship). She now gathers *stern-board* (i.e., starts to sail astern) and continues to back around, turning her stern up into the wind, which operation is facilitated by bracing the after yards like the fore as soon as the wind is abeam. After the wind has passed the stern, the ship gradually gathers headway and comes up to the wind on the new tack, when the operation is completed.

BOX'ING (probably akin to Dan. *bask*, slap, blow, *boske*, to slap, strike). Since the days when fighting with the bare fists was made unlawful, the tendency of the interpretation of the word "boxing" has been to limit its use to exhibitions of skill, and to use the word "pugilism" when referring to professional contests under the old rules and to ancient gladiators. Modern boxing rules, known as the "Queensberry Rules," which govern even professional prize fights, have eliminated the worst features of the pugilism of antiquity and effected a great improvement in modern methods. The ancient method was to make the punishment as cruel as possible by wearing a *cestus* of bronze, several thicknesses of rawhide strongly fastened together and projecting beyond the knuckles, and by binding the wrist and forearm with leather thongs, by these means adding to the capacity of the bare hand to inflict injury. The present custom of wearing a padded glove lessens this capacity. The last remnant of barbarism disappeared from pugilism when wrestling, which played an important part in the contests of the

eighteenth and first half of the nineteenth centuries, was ruled out. How late it lasted is testified by the reports of the historic battles of Mendoza, Bendigo, and Sayers, in which such passages as the following were common: "After a short struggle both men went down, the Tipton Slasher uppermost"; or, "They then closed, and after a short tussle, the Infant threw his man, falling heavily upon him."

How ancient was the practice of pugilism may be gathered from many writings of antiquity. In the roll call at the siege of Troy, Pollux is described as "good with his fists." There are many interesting details of it at the funeral of Patroclus, including the mention of the belt, which is still the emblem of pugilistic championships, and the habit of having such contests as part of a funeral celebration has survived to this day in Siam. Vergil's description of the fight between Dares and the Sicilian Entellus is another classical description of the sport.

Among the English sports of the Middle Ages boxing did not occupy so prominent a place as cudgeling and quarterstaff; and James Figg, whose portrait was painted by Hogarth (and who was supreme between 1719 and 1730), may be considered as the modern father of the "manly art of self-defense." From his time until 1860, when Sayers fought Heenan, the list of champions is unbroken. Up to this period the science of self-defense had made but little progress, and strength and endurance constituted the only recommendations of the practitioners at Smithfield, Moorfield, and Southwark Fair, which had long had booths and rings for the display of boxing. Jack Broughton (1705-89), who occupied the position of "champion of England" from 1784 to 1780, built a theatre in Hanway Street, Oxford Street, in 1740, for the display of boxing; advertisements were issued announcing a succession of battles between first-rate pugilists, who never quitted the stage till one or the other was defeated, the reward of each man being dependent upon and proportioned to the receipts. Broughton was for 18 years champion of England. He propounded some rules for the regulation of the ring which remained in authority till 1838, or nearly a century. They are now spoken of as the "old rules." Rule 1 is, that a square of a yard be chalked in the middle of a stage, and that in every fresh set-to after a fall the seconds are to bring their men to the side of the square and to place them opposite each other; and until this is done, it is not lawful for one to strike the other. Rule 2, that if either of the combatants be unable to be brought up to the square within 30 seconds after a fall and the close of a round, he shall be deemed a beaten man. No man is permitted to hit his adversary when he is down, or to seize him by the breeches, or below the waist, and a man on his knees is to be reckoned down. These rules laid the foundation of fair play. To Broughton also is due the introduction of gloves for "sparring matches," whereby lessons could be taken without injury. The greatest professor of the art was John Jackson (1769-1845) who was champion from 1795 to 1800. He was not only the most scientific boxer of his day, but he gave his art such a prestige and popularity that half the men of rank and fashion of the period were proud to call themselves his pupils. He opened rooms for the practice of boxing in Bond Street,

and for years these were crowded by men of note. His "principles of pugilism" were, that contempt of danger and confidence in one's self were the first and best qualities of a pugilist, that in hitting you must judge well your distances, for a blow delivered at all out of range was like a spent shot, and valueless, that men should fight with their legs, using all possible agility, as well as with their hands, and that all stiffness of style or position was wrong. Jackson is still regarded as one of the best theorists on the art. At this period pugilism was actively supported by many persons of high rank. In 1814, when the Allied sovereigns visited England, among other entertainments, a sparring display was provided under Jackson's management, and the distinguished foreigners expressed much gratification at the exhibition of so much science and fine physical development. Besides Jackson, Belcher, Gully, and Cribb were noted champions at this period, which may be termed the palmy days of the ring. From various causes its decline has since been uninterrupted. The more distinguished patrons gradually withdrew, the Pugilistic Club, which had been established in 1814 and included all the aristocratic patrons of the ring, was broken up. Magistrates set their faces against the lawless assemblies of roughs and pickpockets who latterly formed the greater part of the spectators at prize fights. In 1860, however, the international combat between Tom Sayers, the Englishman, and John Heenan, the American, revived for a moment public interest in the art. This contest was declared a draw, when, after 2 hours and 20 minutes of fighting, the mob rushed the ring and ended the combat. After that prize fights were suppressed in England, and glove contests adopted under the Queensberry rules, which now govern them all the world over. Under these rules wrestling and hugging are prohibited, each round is limited to three minutes with one minute interval, and the time allowed for a fallen man to get up is reduced to 10 seconds. The art thenceforward was vigorously maintained in England by many amateur clubs, among the most important of which was the Amateur Athletic Club, founded in 1886. Tom Sayers retired after the fight with Heenan in 1860, leaving the championship of the world open for competition. Jem Mace, by a series of contests, became entitled to meet J. Allen for it in America in 1870 and defeated him. James Smith became the next champion of England in 1885. He was beaten by Jake Kilrain, of Boston, in 1887, Kilrain becoming the world's heavyweight champion. In 1889 John L. Sullivan, of Boston, defeated Kilrain. This is believed to have been the last contest in the United States under the old rules of the London prize ring. James J. Corbett beat Sullivan in 1892, but was defeated in 1897 by Robert Fitzsimmons, who in his turn was vanquished by James J. Jeffries in 1900 and again in 1902. Jeffries was defeated by Jack Johnson (colored) at Reno, Nevada, in 1910. The art of boxing, as an active and healthy exercise, is likely to be maintained, it is a part of all gymnasium work in the United States, so far as facilities for the exercise are concerned, and it has been taken up by the Amateur Athletic Union, which aims to carry it on as a high-class sport, as distinct from professional pugilism.

In 1911 the New York Legislature enacted a

law (consult Laws of New York for 1911, Chapter 779) authorizing the appointment by the governor of a State Athletic Commission of three members to serve five years, and to have "sole direction, management and control of and jurisdiction over all boxing and sparring matches." This law restricts such contests to ten rounds, prescribes gloves not less than eight ounces in weight, provides that 5 per cent of the total receipts from such exhibitions shall be paid to the State, and requires that they shall be absolutely bona fide competitions. Under this law public boxing matches were resumed, especially in New York City. At about the same time there was a renewal of interest in boxing in Europe, especially in France, where Carpentier and Moreau won recognition as expert pugilists. In December, 1913, at London, Carpentier knocked out in one round the English heavyweight champion, "Bombardier" Wells, who, however, had already been knocked out (in the preceding March) by "Gunboat" Smith, the American sailor, at New York.

On pugilism, consult *Fistiana* (London, 1868), *American Fistiana* (New York, 1876), *Miles, Pugilistica* (3 vols., London, 1863), and for the side of boxing as a sport, O'Reilly, *Ethics of Boxing* (Boston, 1888), Doran, *Self-Defense* (Toronto, 1879), Trotter, *Practical Treatise on Boxing* (Philadelphia, 1900), "Boxing," *Badminton Library* (London, 1886), "Boxing," *Oval Series* (London, 1896), "Boxing," *Spalding's Athletic Library* (New York, published annually), Lynch, *The Complete Amateur Boxer* (London, 1913).

BOXING DAY. A popular term applied to December 26 in England. On that day the gentry were accustomed to give presents, generally of money, to their servants or others of humble life. These presents came to be known as *Christmas boxes*. The custom is, perhaps, traceable to that of the Romans during the season of the Saturnalia (q.v.). A fanciful derivation of the term is to be found in Duntton's *Athenian Oracle* (reprinted by Bell, 4 vols.), London, 1728, but its actual origin is very obscure. The practice has of recent years been regarded as a nuisance and in 1836 was actually legislated against, so far as government employees were concerned. Boxing day is one of the four legal bank holidays, the others being Easter Monday, Whitmonday, and the first Monday in August. Consult Brand, *Popular Antiquities* (ed. by Ellis, 3 vols., London, 1843).

BOXING THE COMPASS. One among many sea phrases whose origin is not easily traceable. It means simply a rehearsal or enumeration of the several points, half-points, and quarter-points of the mariner's compass in their proper order, and is among the lessons which a young sailor has to learn. See COMPASS.

BOXTEL, bôks'tel. A town and important railway junction in North Brabant, Holland, at the confluence of the Beerze and Dommel, 6 miles south of Bois-le-Duc (Map Netherlands, D 3). The church of Saint Peter and the castle of Stapel are the chief buildings. It manufactures damask linens, paper, and salt. In 1794 the French here won an important victory over the Anglo-Dutch army. Pop., 1900, 6743, 1911, 8258.

BOX'THORN', or MATRIMONY VINE. See LYCIUM.

BOX TORTOISE, tór'tis or -tús, or **TURTLE.** See TURTLE.

BOYACÁ, bō'yá-ká'. A department of the Republic of Colombia, South America, bordering upon Venezuela and the states of Santander and Cundinamarca. It covers an area of 16,460 square miles, a large portion of the former area having been incorporated with new departments organized in 1905. In the western part of the old state are Eastern Cordilleras, from which the land slopes east in vast prairies, covered to a great extent with marshes and forests, with scattered pastures and cultivated ground, watered by tributaries of the Orinoco and the Meta. The lowlands are fertile, and among the mountains various minerals are found, and the emerald mines of Muzo have long been famous. The people have rude manufactures of cotton, wool, straw, etc., but cattle raising is the chief occupation. Pop., 380,000. Only a small part of the state is inhabited. The capital is Tunja, of 8500 inhabitants.

BOYACÁ. A town of Colombia, 25 miles south of Tunja in the state of Boyacá, near which in 1819 Bolívar won a victory over the Spaniards, thereby securing the independence of Colombia (Map: Colombia, C 2). Pop., 7000.

BOY AND THE MAN'TLE, THE. A ballad, among those collected by Bishop Percy, which relates that a youth once came to King Arthur's court, bearing a cloak which, he said, only such wiles could wear as had always been faithful.

BOYAR, bō-yār', or **BOJAR** (Russ. *boyarinū*, originally either (1) fighting man, warrior, from *boy*, fight, battle, or (2) great man, for *boyarinū*, from Slav. *bol*, Russ. *bolshoy*, great, grand. The modern Russian form is *barinū*, estate holder, nobleman, master). A word originally of the same meaning as Czech, Lech, and Bolgarin, i.e., free proprietor of the soil. The Boyars in Old Russia were the order next to the kniazes or kniases ('ruling princes'). They formed the immediate "following" of these princes and bore somewhat the same relation to them as the lesser English and Scottish knights of the feudal ages bore to the great barons. They had their own partisans, who served as a kind of bodyguard. They gave their services to a prince of their own choice, whom, however, they left again at their pleasure; and, in consequence of this, the kniazes could secure their allegiance only by the bestowal of privileges. They held exclusively the highest military and civil offices, and the most powerful rulers considered it prudent to use this form of expression in their ukases: "The Emperor has ordered it; the Boyars have approved it." Rank among the Boyars was always proportioned to length of state service and was rigidly observed. This gradation of rank was called *myestintchestvo* (from *myesto*, place at the table during court functions, rank). The institution was peculiar to Slavic life, equally unlike feudalism and modern aristocracy, and must be regarded as a strictly national development. In their housekeeping the Boyars were excessively fond of splendor, and their contempt for the serfs, or "lower orders," was immeasurable. In the lapse of time many Chinese customs—as might be expected from their theory of rank—crept into their public life. Their power, and the respect which was paid them, acted as a wholesome check upon the otherwise unbridled authority of the princes; in consequence of which the latter became their bitter enemies and often sought to destroy their power. This was

finally done by Peter the Great, who abolished the order of Boyars, giving them a place among the Russian nobility, but stripping them of their peculiar privileges. The last Boyar, Kniaz Ivan Yuryevitch Trubetskoy, died Jan. 16, 1750. In Rumania Boyars still exist. Consult: Rambaud, *History of Russia*, Eng. trans., by Well (London, 1887); Wallace, *Russia* (2d ed., New York, 1905).

BOY BISH'OP. The custom of electing a boy bishop on St. Nicholas' Day dates from a very early period. In England it seems to have prevailed in many parishes. The election took place on St. Nicholas' Day (December 6), and the authority lasted until Holy Innocents' Day (December 28). The boy bishop was usually chosen from the children of the church or cathedral choir, but the custom also prevailed in the schools of Winchester and Eton. He was arrayed in episcopal vestments and, attended by a crowd of subordinates in priestly dress, went about with songs and dances from house to house, blessing the people. The boy bishop was supposed to exact implicit obedience from his fellows, who with their superior took possession of the church and performed all the ceremonies and offices except mass. The custom found countenance not among the populace only. In 1299 it is said that Edward I., on his way to Scotland, permitted a boy bishop to say vespers before him at Heton, near Newcastle-on-Tyne, and gave him and his companions a present. At Salisbury, and perhaps in other places also, the boy bishop—so it is said—had the power of disposing of such prebends as happened to fall vacant during the days of his episcopacy; and if he died during his office, the funeral honors of a bishop, with a monument, were granted him. In England the custom of electing a boy bishop was abolished in the reign of Elizabeth, though it seems to have lingered here and there in villages till about the close of her reign. Consult Walcott, *Sacred Archaeology* (London, 1868).

BOY'COTT, BOY'COTTING. A conspiracy to punish or coerce any one by inducing others to abstain from business or social relations with him. A species of organized ostracism. It derives its name from a conspicuous victim of the practice, Captain Boycott, an Englishman, who was land agent of Lord Erne in the district of Connemara, Ireland, in 1881. He incurred the ill will of the tenantry by his harsh enforcement of the law in the eviction of tenants for nonpayment of rent. As a consequence they induced the population for miles around to refuse to have anything to do with him or his family. He was reduced to dire straits and was finally obliged to leave the country.

The boycott is not infrequently employed in trade disputes by combinations of working men or trades unionists to injure the business of an obnoxious employer with the view of forcing him to accede to the demands of his employees or of the trades unions, or of punishing him for his refusal so to do. It has generally been held that this form of coercion, if employed for a lawful purpose, as to secure a rise in wages or better working conditions or generally to improve the condition of the working classes, and if carried on without violence or other acts in themselves unlawful, is not an illegal conspiracy; in other words, that "peaceful" boycotting, no matter how much injury it may inflict on the victim, is not forbidden by law.

This is the doctrine of the English courts, and it has been affirmed by Parliament in the Trade Disputes Act (6 Edw VII, c 47, 1906). In many of the United States the contrary view has, however, been taken, and it is there held that a boycott, even when unaccompanied by violence or intimidation, is unlawful, and in some States it is prohibited by statute. When employed for an improper purpose, as merely to injure an obnoxious person, or when accompanied by violence or other unlawful act, boycotting is everywhere unlawful and subjects the offenders to an action for damages as well as to indictment and punishment by the criminal law.

Consult articles by Jeremiah Smith, "Crucial Issues in Labor Litigations," *Harvard Law Review*, vol. xx, pp. 253, 345, 429 (1907), and by O W Holmes, "Privilege, Malice, and Intent," *ib*, vol. viii, p 1 (1893), and see COMPETITION, CONSPIRACY, INTIMIDATION, TRADES UNIONS.

BOYD, ANDREW KENNEDY HUTCHISON (1825-99) A Scottish divine and author, born at Auchmleck, in Ayrshire. He studied at King's College and at the Middle Temple in London, and took his bachelor's degree at Glasgow (1846). Licensed to preach in 1850, he became in 1851 minister of Newton-on-Ayr. In 1859 he gained a wide reputation for his *Recreations of a Country Parson*, contributed to *Fraser's Magazine*, and in the same year was appointed to St Bernard's, Edinburgh, in 1865 becoming minister at St Andrews. For the part he played in literature and in the Church councils he was soon the best known among the Scottish divines of his day. *The Recreations of a Country Parson* (1859, 1861, 1878) appeared in three series. He published an extremely interesting series of autobiographical sketches bearing the titles *Twenty-five Years of St Andrews* (1892), *St Andrews and Elsewhere* (1894), *Last Years of St Andrews* (1896). Among his other publications are *Graver Thoughts of a Country Parson* (1862), *Autumn Holidays of a Country Parson* (1864), *Critical Essays of a Country Parson* (1865), *East Coast Days and Memories* (1889).

BOYD, SIR JOHN ALEXANDER (1837-) A Canadian jurist, born in Toronto, and educated at Upper Canada College and Toronto University. He was admitted to the bar in 1863 and came to be recognized as one of its ablest equity pleaders. In 1881 he was appointed Chancellor of Ontario, and in 1887 president of the High Court of Justice for that province. He served also as arbitrator for the Dominion government in the adjustment of certain claims made against it by the Canadian Pacific Railway and in 1902 arbitrated the differences between this road and its trackmen. He was also a member of various royal commissions. One of the ablest of Canadian judges, he became distinguished for decisions swiftly reached, clear, impartial, and models of style. In 1901 he was knighted.

BOYD, JOHN PARKER (1764-1830) An American soldier, born at Newburyport, Mass. He entered the United States army in 1786, went in 1789 to India, and there organized a small mercenary force, retained in the service of various native princes. Having returned to the United States in 1808, he was in the same year appointed colonel of the Fourth Infantry, and in 1811 distinguished himself at the battle of Tippecanoe. During the War of 1812, with

the rank of brigadier general, he was notably prominent at the capture of Fort George, Canada, and at Chrysler's Field. He published a pamphlet, *Documents and Facts Relative to Military Events during the Late War* (1816), containing the text of a memorial communicated to the War Department in protest against his nonretention as an officer in the peace establishment. Just before his death he was appointed naval officer at Boston by President Jackson.

BOYD, ZACHARY (1585-1653) A Scottish divine. He was born at Penkill, Ayrshire, Scotland, about 1585, was educated at Kilmarnock, and studied at the universities of Glasgow and St Andrews and the Protestant College of Saumur in France, of which latter he was in 1611 appointed a regent or professor and is said to have declined the principalship. The persecutions of the Protestants in France caused him to return to Scotland in 1623, and he became minister of the Barony Parish, Glasgow, and was thrice elected rector of the university of that city. His principal prose work, *The Last Battell of the Soule in Death*, was published at Edinburgh in 1629, in 2 vols. He was author of 18 other works, chiefly of a religious cast. His *Bible Songs* and his *Psalmes of David in Meter* appeared at Glasgow in 1648. He died in 1653, leaving numerous manuscripts and his library, with a considerable legacy, to the University of Glasgow, and his bust is now preserved in its library. Among his manuscripts is a collection of quaint poems on scriptural subjects, entitled *Zion's Flowers*, usually called Zachary Boyd's Bible. Gabriel Neil reprinted at Glasgow, in 1831, Boyd's *Last Battell*, and published a life of Boyd, in 1855, with four poems from *Zion's Flowers*. *Four Letters of Comforts for the Deaths of the Earle of Hadningtown and of the Lord Boyd*, originally 1640, were reprinted in facsimile at Edinburgh, 1878.

BOYD-CARPENTER, SIR WILLIAM See CARPENTER, SIR WILLIAM BOYD.

BOYDELL, JOHN (1719-1804) An English etcher and publisher of prints. He was born at Dorrington, Shropshire, Jan. 19, 1719, studied etching with W H Towns in London, and attained a certain proficiency in the art. But he is best known as a publisher of the prints of others. The works of British engravers, through his patronage, rose to such a high degree of excellence that they were sought after by all Europe, and the importation of foreign prints at that time in a great measure ceased. He then directed his attention to the art of painting, undertaking to illustrate Shakespeare from the works of English artists. In bringing this project to completion he expended £30,000, and no less than 170 pictures were required. His Shakespeare Gallery was ready for the public in 1789, but the Napoleonic wars destroyed his foreign trade and brought him into such financial straits that in 1804 he obtained permission from the Parliament to sell all his artistic property by lottery, but Boydell died before the lottery was held. In 1782 he was elected alderman and in 1790 Lord Mayor. At a Royal Academy dinner in 1789 Sir Joshua Reynolds toasted him as the "commercial Mæcenas of England."

BOYDEN, SETH (1785-1870) An American inventor, born in Massachusetts. He invented a machine for splitting leather and a process for making spelter. In 1826 he made

the first malleable cast iron. Among his other inventions was one for making hat bodies, and a process for making Russia sheet iron. He built the first successful locomotive that had the cylinders outside of the frame, and with the "cut off" instead of the throttle valve. His later years were spent in farming in New Jersey, where his ingenuity manifested itself by developing new varieties of strawberries.

BOYD'S. The courtyard in front of the White Horse Inn, where Dr. Johnson alighted on his first arrival in Edinburgh, as narrated by Boswell. It has since been swept away to make room for modern houses and streets.

BOYE, bô'ye, CASPAR JOHANNES (1791-1853). A Danish preacher and poet, born at Kongsberg, Norway. He studied theology in Copenhagen, was pastor of various parishes, and from 1847 in Copenhagen. He was known as a translator of Walter Scott, but established a reputation, first anonymously, by his dramas, the best of which are the three tragedies, *Juta* (1823), *Svend Grathe* (1824), and *Erik den Syvende* (1827). In Danish literature his rather sentimental works stand between the more healthy and vigorous Oehlenschläger and early modern realism. Selections from his poetic works appeared at Copenhagen (4 vols., 1850-51).

BOYEN, bô'yen, HERMANN VON (1771-1848). A Prussian field marshal. He was born at Kreuzburg, East Prussia, and was descended from an ancient noble family of Bohemia. In 1809 he entered the War Department of the Prussian government, where he counseled the abolition of the militia system and the introduction of general military duty. As director of the War Department he acted as the confidential adviser of the king from 1810 to 1812. He was afterward appointed Prussian Minister of War, in which capacity he introduced the law of compulsory military service (Sept. 3, 1814). From 1819 he lived in retirement for 21 years, then reëntering active service as general of infantry and in the following year becoming again Minister of War. Upon his second retirement in 1847 he was raised to the rank of field marshal. His services in behalf of Prussia were recognized in an address by Emperor William I to the senior members of the Order of the Iron Cross, March 31, 1871. The Emperor said: "Recognizing that we have only built upon the foundations laid in 1813, 1814, 1815, we should fitly appreciate the splendid services of the men of that epoch, and notably those of Boyen."

BOYER, bô'wâ'yâ, ALEXIS, BARON DE (1757-1833). A French surgeon. He was a barber surgeon's apprentice, then studied medicine, and soon won recognition. In 1787 he was appointed second surgeon to the Hôpital de la Charité at Paris, and afterward was professor, first of operative surgery and then of clinical surgery, at the Ecole de Santé. In 1804 he was appointed first surgeon to Napoleon. After the Restoration Boyer became professor of practical surgery in the University of Paris and first surgeon at the Hôpital de la Charité. In 1823 he was appointed consulting surgeon to the king and in 1825 was admitted a member of the Institute. His best-known works are his *Traité complet d'anatomie* (4 vols., 1797-99) and *Traité des maladies chirurgicales et des opérations qui leur conviennent* (11 vols., 1814-26; new ed., 7 vols., 1844-51).

BOYER, JEAN BAPTISTE DE. See ARGENS, MARQUIS D'.

BOYER, JEAN PIERRE (1776-1850). A general and President of the Republic of Haiti. He was a mulatto. He was born at Port-au-Prince, received a European education, and in 1792 entered the military service. After his return to Haiti he joined the blacks, who had risen against the French. After the commissioners of the French Convention had proclaimed the freedom of the blacks in Haiti (1793), he fought with the mulattoes against the negroes and with the negroes against the English. He was compelled to flee to France, but returned with General Leclerc in 1802. After the French had been expelled, and negro domination established, Boyer united with Pétion and Christophe to overthrow Dessalines, the negro despot; but when Christophe made himself Emperor, Pétion established an independent republic in the southwestern part of the island, and Boyer became Governor of Port-au-Prince, and the firmest adherent of the new commonwealth, which he defended against the troops of Christophe. Upon the death of Pétion, in 1818, Boyer was unanimously elected President. Within three years he brought the entire island under his rule, and in 1825 obtained from France the recognition of the Haitian Republic. At first the country improved under his administration, but power corrupted him. His cruel and arbitrary conduct aroused great discontent, and the imposition of oppressive taxes necessitated by the payment of an indemnity of 150,000,000 francs to France stirred up an insurrection in 1843. Boyer fled to Jamaica, and, after the Revolution of 1848, retired to France, where he died. See HAITI.

BOYËSEN, HJALMAR HJORTH (1848-95). A Norwegian-American novelist and littérateur. He was born at Fredriksvern, Norway, Sept. 23, 1848, and studied in Christiania and in Leipzig. In 1869 he came to America, edited the *Fremad*, a Scandinavian journal, in Chicago, became professor of German at Cornell (1874-80), and held a professorship in Columbia University, New York, from 1880 till his death. He acquired a facility in English remarkable in a foreigner, and within six years of his emigration had achieved popularity in English prose and verse. His more noteworthy works of fiction are: *Gunnar, a Norse Romance* (1874); *Tales from Two Hemispheres* (1874); *Falconberg* (1878); *Ilka on the Hilltop* (short stories, 1881); *Queen Titania* (1881); *A Daughter of the Philistines* (1883); *Social Struggles* (1884); *The Golden Calf* (1892). His critical essays are contained in *Goethe and Schiller: Their Lives and Works* (1878); *Literary and Social Sketches; Essays on Scandinavian Literature; and Essays on German Literature*. His poems are gathered in *Idylls of Norway* (1882). He also wrote negligible juveniles. As a popular lecturer he was in great demand. *Ilka on the Hilltop* was dramatized in 1884, and a play of his called *Alpine Roses* was produced in the same year. He died, suddenly and alone, in New York, Oct. 5, 1895.

BOYLE. A town in Roscommon Co., Ireland, picturesquely situated in a valley on both sides of the Boyle, 1 mile above Lough Key, and 8 miles northwest of Carrick-on-Shannon (Map: Ireland, C 3). It is noted for its well-preserved Cistercian abbey (1161), of considerable architectural interest, and is a favorite angling centre. It has a large grain and butter trade. Latin and English annals of Boyle, dating from

420 to 1245, have been published. Pop., 1901, 2477, 1911, 2691

BOYLE, BERNARDO See **BOIL, BERNARDO**

BOYLE, CHARLES, fourth EARL OF ORRERY (1676-1731). An English soldier and physicist. He was born at Chelsea, was educated at Christ Church, Oxford, succeeded to his title in 1703, fought at Malplaquet, was made major general, and received several court appointments. He died Aug. 28, 1731. After him was named the astronomical instrument known as the "Orrey." Boyle is chiefly remembered for the part he took, while a student, in the controversy over the antiquity of the *Epistles of Phalaris*. He was silenced by Richard Bentley. The literary quarrel led to Swift's *Battle of the Books*. Of his poems, Sir Richard Blackmore said

"After his foolish rhymes, both friends and foes
Conclude they know *who did not write his prose*."

See **BATTLE OF THE BOOKS**

BOYLE, DAVID (1842-1911). A Canadian ethnologist. He was born in Greenock, Scotland, and was educated there and at St. Andrew's School, Birkenhead, England. In 1856 he went to Canada with his parents, and within a few years began teaching. While principal of the public school at Elora, his researches in the geological formation of the district led to the discovery of important fossils, named after him "Murchisonia Boylei." His archaeological researches resulted in a valuable collection, chiefly Indian relics, which was presented to the Canadian Institute, Toronto, and was the basis of its archaeological museum. He had charge of the Ontario mineral exhibit at the Cincinnati Centennial Exposition (1888), and also at the Imperial Institute, London (1892), and the Columbian Exposition (1893). He was appointed superintendent of the Education Department Museum, Toronto, in 1901. In recognition of his attainments he was chosen a member of various learned societies in Europe and America. He published *Notes on the Life of Dr. Joseph Workman* (1894), *Notes on Primitive Man in Ontario* (1895), *The History of Scarborough, 1796-1896* (1896), and *Uncle Jim's Canadian Nursery Rhymes* (1908).

BOYLE, JOHN, EARL OF CORK AND ORRERY (1707-62). An Irish writer. He is best known for his strangely unappreciative and malicious *Remarks* (1751) on his dead friend Swift and for his excellent rendering into English (1751) of the *Epistolæ* of Pliny the Younger.

BOYLE, RICHARD (1566-1643). The founder of the house of Cork and Orrery, and styled the "great Earl of Cork," was born at Canterbury, England. He was educated at Bennet's (Corpus Christi) College, Cambridge. At the age of 22 he went over to Ireland, where he afterward bought estates and improved them, promoted the immigration of English Protestants, and triumphed over his accusers and enemies through the intervention of Queen Elizabeth. In 1616 he was made Baron Youghal and in 1620 became Viscount Dungarvan and Earl of Cork. In 1631 he was made Lord High Treasurer, an office which remained hereditary in his family. In his old age he suppressed a rising of Munster rebels.

BOYLE, ROBERT (1627-91). An English physicist and chemist. He was the son of the first Earl of Cork and was born at Lismore Castle, Waterford, Ireland, Jan. 25, 1627. As a child, he was distinguished by precocity of in-

tellect and a rare love of truth. After studying at Eton and at home, he went to the Continent, where he stayed for six years (1638-44). On his return he found himself in possession, by his father's death, of the manor of Stalbridge, Dorsetshire, where he resided till 1650. He took no part in political strife, but devoted himself to the cultivation of science, and particularly of chemistry and natural philosophy. He was one of the first members of that association of scientific men which about that time (1645) held private meetings at Oxford and London and some years after became better known as the Royal Society. In 1654 he settled at Oxford. Here he experimented extensively in pneumatics and improved the air pump. At the same time he devoted considerable study to theology. After the Restoration he was urgently advised by Lord Clarendon to take orders, but he thought that he could do better service to religion as a layman. Among the proofs which he gave of this, besides his own theological writings and eminent example, were his exertions as Governor of the Corporation for the Spread of the Gospel in New England, as well as in procuring and circulating at his own expense translations of the Scriptures, and his bequest for the foundation with £50 of the "Boyle Lectures" (qv) in defense of Christianity. In 1668 he took up his residence permanently in London and was thenceforth able to devote much of his time to the business of the Royal Society. In 1680 he was chosen president, but declined the honor. A peerage had repeatedly been offered to him and declined. In 1688, finding his health failing, he shut himself up against all interruption, in order to husband his remaining time for the labor of repairing the loss caused by the accidental destruction of his manuscripts. In 1689 his failing health induced him to lessen his activities in various directions, and on Dec. 30, 1691, he died in London. Boyle was tall and emaciated in person and extremely temperate in his habits, often subject to low spirits, but naturally lively and of rare conversational powers. His scientific reputation was unrivaled among his contemporaries, who regarded him as the successor to Bacon's primacy in such matters. His work in science is fully discussed under **CHEMISTRY**. See also **BOYLE'S LAW**. Boyle's style in writing was verbose. His complete works (including his very interesting correspondence), with a life by T. Birch, and an index, were published in 5 vols. (London, 1744, 6 vols., 2d ed., 1772). For his life, see Muir (New York, 1911).

BOYLE, ROGER (1621-79). An English soldier, statesman, and author. He studied at Trinity College, Dublin, and was at first a partisan of Charles I, but subsequently served under Cromwell, of whose Privy Council he became a member. After Cromwell's death he gained control of Ireland for Charles II and upon the Restoration was made Earl of Orrery. He wrote *Parthenissa* (1665-67) and *A Treatise of the Art of War* (1677), besides several plays and a large number of poems.

BOYLE LECTURES. An annual course of lectures delivered at St. Mary-le-Bow Church, London, so called from the founder, the Hon. Robert Boyle (qv), who settled an annual salary of £50 charged upon his dwelling house in St. Michael's, Crooked Lane, London, for "some preaching minister," who shall preach eight sermons in the year for proving the

Christian religion against atheists, deists, pagans, Jews, and Mohammedans, not descending to any controversies among Christians themselves. Archbishop Tenison procured a yearly salary of £50 to be charged upon a farm at Brill, Bucks, instead of the original charge for the endowment. The office is tenable for three years.

The first series of lectures, *A Confutation of Atheism*, was preached in 1692 by Richard Bentley (q.v.). In 1704 Dr. Samuel Clarke preached the lectures, entitled *A Demonstration of the Being and Attributes of God*, in answer to the arguments of Hobbes, Spinoza, and their followers. All the lectures preached up to 1732 were collected into a fine folio edition, in 3 vols. (London, 1739); since that period, till recently, few of the lectures have been published, but among them may be mentioned: F. D. Mauries, *The Religions of the World* (1846; 4th ed., 1862); C. Merivale, *The Conversion of the Roman Empire* (1864); *The Conversion of the Northern Nations* (1865); E. H. Plumptre, *Christ and Christendom* (1866); J. A. Hessey, *Moral Difficulties Connected with the Bible* (3d series, 1871-73); H. Wace, *Christianity and Morality* (1874; 5th ed., 1882); W. C. E. Newbolt, *The Gospel of Experience; or, the Witness of Human Life to the Truth of Revelation* (1895).

BOYLE'S FUMING LIQUOR, or VOLATILE LIVER OF SULPHUR. A mixture of various ammonium polysulphides. It is obtained in the form of a dark yellow, strongly fuming liquid with a pungent odor of hydrogen sulphide, by distilling a mixture of 1 part of sulphur, 2 parts of ammonium chloride, and 3 parts of lime.

BOYLE'S LAW. A law of physics formulated by Robert Boyle, which states that when a gas is at a constant temperature the product of the pressure and volume of a given mass remains constant. The same discovery was also made by the French physicist Mariotte, and the law is sometimes called Mariotte's Law, or the Law of Boyle and Mariotte. See ELASTICITY; HEAT; CRITICAL POINT.

BOYLSTON, boyl'ston, ZABDIEL (1680-1766). An American physician, born in Massachusetts. He was the earliest advocate in the United States of inoculation for smallpox, but the whole profession opposed him, and a law, afterward repealed, was passed against the practice. He secured the support of several prominent ministers, however, and the practice gradually became general in New England. He wrote several pamphlets on inoculation and several papers in the *Philosophical Transactions of London*. Consult an article, "Zabdiel and John Boylston," in vol. xxxv of the *New England Historical and Genealogical Register* (1881).

BOYNE, boin (Ir. *Boinn*). The most important river in the east of Ireland, rising in the Bog of Allen, and flowing through Kildare, King's Co., Meath, and Louth (Map: Ireland, E 3). It passes Trim, Navan, Slane, and Drogheda, and enters the Irish Sea 4 miles below the last town, after a course of over 70 miles, its total descent being 336 feet. Its chief tributaries are the Deel, Mattoch, and Blackwater. It is navigable for vessels of 250 tons to Drogheda and for barges of 70 tons to Navan, 19 miles up. Sand bars prevent large vessels from entering the river. Turgesius, the Dane, sailed up the Boyne in the year 838 and plundered

Meath. It is chiefly famous for the battle of the Boyne (q.v.), which took place on its banks near Drogheda in July, 1690. Consult Wilde, *The Beauties of the Boyne and the Blackwater* (Dublin, 1869).

BOYNE, BATTLE OF THE. A battle fought on July 11 (new calendar; July 1, old style), 1690, 3 miles west of Drogheda, on the banks of the Boyne, Ireland. This battle was fatal to the cause of James II and assured the ascendancy of Protestantism in England. The troops of James, 30,000 in number, were defeated with a loss of 1500 by the forces of William III (James's son-in-law), who had about the same number of men, but lost only about 500. An obelisk, 150 feet high, marks the scene of the battle. For the bitter feeling among the Irish which followed this battle, see ORANGEMEN. The anniversary of the battle of the Boyne is celebrated on July 12.

BOYNE CITY. A city in Charlevoix Co., Mich., 181 miles by rail north of Grand Rapids, at the mouth of Boyne River, at the head of Pine Lake, and on the Boyne City, Gaylor, and Alpena Railroad (Map: Michigan, D 3). Boyne City has a splendid natural harbor and carries on a considerable trade in fruit, sole leather, and hard wood. It has railroad repair shops, foundries, a tannery, a cooperage, flooring, and veneering plant, and manufactures handles, chemicals, and clay products, and extracts. The water works are owned by the municipality. Pop., 1900, 1912; 1910, 5218.

BOYNTON, HENRY WALCOTT (1869-). An American author, born in Guilford, Conn. He graduated from Amherst College in 1891 and thereafter was head of the English department at Phillips Andover Academy for several years. Much of his best work was done as a book reviewer, notably for the *Atlantic Monthly* in 1901-04 and afterward for the *New York Times*. He edited many texts for secondary-school use and a valuable one-volume edition of Pope's *Poetical Works* (1902); wrote brief biographies of Washington Irving (1901) and Bret Harte (1903); *Journalism and Literature, and other Essays* (1904); *A Reader's History of American Literature* with T. W. Higginson (1903); and *The World's Leading Poets* (1912).

BOYRON, MICHAEL. See BARON, MICHAEL.

BOYS, SHIPS'. In nautical language, all the young or green hands on board, so called without much reference to their age. In recent times arrangements have been made to give a more precise meaning to the term by engaging boys or lads as part of the crew. There has been no such rating in the United States navy since the establishment of the apprentice system, but it is still preserved in the British navy.

BOYS' CLUBS. A term applied to organizations maintained by adults on behalf of boys. The spontaneous organizations formed by boys are also occasionally called clubs. An investigation, made by Dr. H. D. Sheldon in 1898, of 862 clubs formed by American boys between the ages of 10 and 17, revealed the following as to their purpose: 23 were secret societies, 28 social ("good times"), 56 industrial, 10 philanthropic, 28 literary, art, and musical, 105 predatory (hunting, fighting, preying, etc.), 379 athletic and game clubs. The majority of these were started by boys of the ages 11, 12, 13, the numbers being (11) 155; (12) 164; (13) 188. Eighty-seven per cent of the clubs were formed by boys between the ages of 10 and 15,

while 85½ per cent stood for physical activity. It was found that interest in athletic organizations increased to the thirteenth year, then rapidly diminished, while interest in literary societies, etc., increased with maturity. Boys and girls seldom joined in forming clubs. A more detailed investigation of 66 boys' "gangs" by J. Adams Puffer, showed somewhat similar results. Eighty per cent included group games among their activities, 74 per cent, "tribal industries" (hunting, fishing, building huts, etc.), 74 per cent, stealing and injuring property, 70 per cent, fighting.

Boys' clubs promoted by adults represent an endeavor to utilize to better purpose the instincts that lead boys to band together. In all such clubs an attempt is made to provide wholesome amusement, especially in the form of gymnastic exercise and outdoor sports, to establish standards of honesty and discipline. To supplement the work of the public schools in creating an interest in good reading is also a common object of such clubs. Religious instruction plays a large part in many of the organizations. The earlier clubs, many of which were founded in the last quarter of the nineteenth century, were large, numbering their members by hundreds. In some cities large club buildings have been erected. Such clubs are still the prevailing type in England. Especially in Manchester, clubs of 500 members or more thrive. Such organizations have been criticized, perhaps too severely, on the ground that the boys do not come into intimate contact with the leader. Another type of club came into existence with the social settlements, the first of which in the United States was started in 1889. The clubs are small (8 to 12 members) and hold regular meetings once or twice a week, the programme being varied to suit the boys' interests, or individual clubs take up specific courses. The boys are usually of one locality and often are friends. Thus they are interested in one another, and the leader has a chance to come into close contact with them all. Both types exist in American cities, but in this country the tendency is toward the small clubs. It is estimated that nearly 100,000 boys in America, and 25,000 in England, are members of boys' clubs. Consult Johnson, "Rudimentary Society among Boys," in *Johns Hopkins University Studies*, 2d series, No. 11 (Baltimore, 1884), Sheldon, "The Institutional Activities of American Children," reprint (Worcester, 1899) from *American Journal of Psychology*, vol. ix, Johnson, *Games and Play*, Social Work Monographs (Boston, 1898), Forbush, *How to Help Boys* (Boston, 1900), ib, *The Boy Problem* (Boston, 1901), Newman, *The Boys' Club in Theory and Practice* (London, 1900), Buck, *Boys' Self-Governing Clubs* (New York, 1903), Russell and Rugby, *Working Lads' Clubs* (London, 1908), Swift, *Youth and the Race* (New York, 1912), Forbush, *The Coming Generation* (New York, 1912), Puffer, *The Boy and his Gang* (New York, 1912).

BOY SCOUTS. A movement started for the general purpose of training boys between 12 and 18 in self-reliance, manhood, and good citizenship. It was begun in England in 1908 by General Sir Robert S. S. Baden-Powell, who was impressed by the fact that 45 per cent of the boys of England were growing up without any knowledge of useful occupations. The idea at once received popular support in England, and within two years and a half from the foundation of

the first society 150,000 boy scouts had been enrolled.

In the United States there were at this time two organizations founded for the general purpose of upbuilding the character of boys by grounding them in the principles of good morals and instructing them in useful occupations. One of these organizations was founded by Ernest Thompson Seton and was called Woodcraft Indians, and the other, founded by Dan C. Beard, was called the Sons of Daniel Boone. In 1910 these organizations were combined under the general title Boy Scouts of America and chartered under the laws of the District of Columbia Feb. 8, 1910.

The aim of the Boy Scout movement is in general to supplement the various existing educational agencies and to promote the ability of boys to do things for themselves and for others. The method is made up in the term called "scoutcraft," and is a combination of observation, deduction, and handiness. It includes first aid, life-saving, tracking, signaling, cycling, nature study, seamanship, and other instruction. Each body of scouts, which is known as a patrol, selects a leader from among its own members. Several patrols are combined in a troop, and for these is appointed a scout master who is the leader of the troop. The scout master must be a person of influence and possess qualities which boys respect. Before he becomes a scout a boy must take the scouts' oath, which is as follows: "On my honor I promise that I will do my best, 1st, to do my duty to God and my country, 2d, to help other people at all times, 3d, to obey the scout law." The scouts are divided into three classes—tenderfoot, second-class, and first-class scout. Passing from the tenderfoot class to the second and first class, the boy must pass certain tests. The test for a first-class scout includes the ability to swim 50 yards, the possession of at least two dollars in a savings bank, signaling, the ability to go on foot or to row a boat well to a point seven miles away and return, the ability to describe or show the proper means of saving a life in case of accidents of various kinds, the ability to cook satisfactorily a prescribed variety of dishes, the ability to read a map correctly and draw an intelligent rough sketch map, the ability to use an ax for felling or trimming light timber, the ability to judge distance, size, numbers, and height within 25 per cent of error. The rules of conduct of the scouts are described in the scout law. These prescribe honor, loyalty, unselfishness, friendliness, hatred of snobbishness, courtesy, kindness to animals, obedience to parents, gentleness, and thrift. Although the organization is on military lines, the Boy Scout movement is a non-militant one. A prescribed uniform is worn, and medals are given for faithful services.

At the end of 1913 there were about 8000 scout masters representing as many organizations. The approximate membership of the Boy Scouts of America at that date was 300,000. In the latter part of 1911 and the first part of 1912 Sir Robert Baden-Powell visited the United States and lectured on the Boy Scout movement.

The Boy Scout movement has received the general support of all the religious denominations and other social and economic bodies. The honorary president of the Boy Scouts of America is President Woodrow Wilson, honorary vice presidents, William H. Taft and Theodore Roosevelt, President, Cohn H. Livingstone, Chief Scout,

est Thompson Seton; and National Scout Commissioner, Daniel Carter Beard.

Kindred organization known as the American Scouts was organized in May, 1910. The name was later changed to the United States Scouts. It is chiefly local in New York.

BOYSSET, bwa'sá', CHARLES (1817-1901). French legislator, born at Châlons-sur-Saône, entered the Legislative Assembly after the revolution of 1848 and served until 1851, when was banished in consequence of the coup d'état. In 1867 he returned to Paris and in 1870 was commissioned to organize the national guard in the departments of Côte-d'Or and Maine-et-Loire. He became a member of the Radical Republican party in the Chamber of Deputies, where he proposed such measures as the separation of church and state and the abrogation of the protectionist laws. He published the known *Catéchisme philosophique du XIX^e siècle* (1868) and collaborated with Proudhon *Le Peuple*.

BOYTHORN, LAWRENCE. In Dickens's *the House*, a character supposed to represent the Savage Landor.

BOZ. The pen name of Charles Dickens in a set of papers now known as *Sketches by Boz*, which appeared in book form in 1836. The number to which this name was signed appeared in the *Monthly Magazine* for August, 1836. Dickens's own explanation is interesting: "Boz" was the nickname of a pet child, a younger brother (Augustus), whom I had dubbed Boz in honor of the Vicar of Wakefield; which he facetiously pronounced through the nose as Bozes, and being shortened became Böz, usually the "o" came to be pronounced short, Böz is now correct. The *Pickwick Papers* appeared ascribed to "Boz."

OZEMAN, böz'man. A city and the county of Gallatin Co., Mont., 98 miles southeast Helena, on the Gallatin River and on the Northern Pacific, and the Chicago, Milwaukee, and St. Paul railroads (Map: Montana, E 4). Ozeman is the seat of the State College of Agriculture and Mechanic Arts, opened in 1893, and contains a public library and fine county and municipal buildings. It is in a region which has valuable deposits of coal, onyx, and building stone, and is the headquarters of large agricultural and stock-raising interests. The industrial establishments include flour mills, lumber mills, elevators, a brewery, and a foundry. A line some 20 miles in length has been constructed to serve both for irrigation and as an artery. The water works are owned by the city.

Pop., 1890, 2,143; 1900, 3,419; 1910, 5,107.
OZEN, or **BOZEN**, bö'tsen (It. *Bozano*). A town of the Austrian crownland of Tirol, situated about 800 feet above sea level, at the junction of the Taffer and the Eisach, about 83 miles south of Innsbruck (Map: Austria, B 3). It is well built, and protected from inundations by the Taffer by a strong wall about 2 miles in length, which at the same time serves as a pleasant promenade. The houses for the most part are built in the Italian style, many of them with arcades. The chief public buildings are the town hall, the Gothic parish church, and the Franciscan Monastery, the latter two dating from the fourteenth and fifteenth centuries. Its situation on the Brenner Railway and at the junction of the roads from Germany, Italy, and Switzerland, makes Bozen the busiest commercial

town in Tirol. Its trade is chiefly in fruit and wine, the latter being known as early as the seventh century. There are factories for the canning of fruit and vegetables. Bozen is supposed to occupy the site of the ancient Roman Pons Drusi. Adjoining Bozen, on the opposite side of the Taffer River, is the popular winter resort of Gries. It came into the possession of Austria in 1531. Pop., 1910, 24,126.

BOZ'RAH. The name of two biblical cities—one a city of Edom, the other of Moab. 1. Bozrah, the capital of Edom (Gen. xxxvi. 33; Isa. xxxiv. 6, etc.). This city seems to be identical with El-Buseireh, north of Petra and southwest of Tafilah, in the district of Jebel. Amos (i. 12) predicts the destruction of this city in his prophecy of the doom of Edom, and it is also mentioned in Jer. xlix. 13, 22. 2. Bozrah of Moab, mentioned in the prophecy of the doom of Moab in Jer. xlviii. 24, has not been certainly identified. It may be Bosrah esh-Sham, in the district of Hauran (Auranitis), the Bostra of the days of Trajan. This place is a vast collection of ruins, about 76 miles south-southeast of Damascus. In 100 A.D. the city was restored and beautified by Trajan, who made it the capital of the province of Arabia. In the reign of Alexander Severus it was made a colony, and later it was the seat of a bishopric and of an archbishopric. During the Crusades it was held by the Mohammedans, and all attempts of the Crusaders to capture it were futile.

BOZZARIS, bö'tsä-räs; popularly, bö-zä-räs, Marco or Marcos Bozzaris (c.1790-1823). The "Leonidas of Modern Greece." He was born at Sulis, in the mountains of Epirus, about 1790. After the Treaty of Tilsit, in 1807, he entered the French service, but in 1821 he threw himself into the Greek struggle for liberation, and at the head of a band of Suliotas took an active part in the engagements with the Turks, winning many victories. In 1822 he was defeated at Petta (in company with Prince Mavrocordatos), chiefly through treachery, and both the patriot leaders were obliged to take refuge at Missolonghi. This place valiantly held out until relieved by a Hydriot fleet. In 1823 in anticipation of an assault which he knew the fortifications of Missolonghi were too weak to withstand, he made a sudden sally upon the Turks during the night of August 20, at Karpenisi. The Turkish army was so far superior that its van alone was many times larger than the attacking party; but the Greeks threw the Turks into utter confusion and won a complete victory. The triumph was saddened by the loss of the heroic Bozzaris, who fell while leading on his men to the final attack. This battle has been made the subject of a poem by Fritz-Greene Halleck. Consult: Mendelssohn-Bartholdy, *Geschichte Griechenlands* (Leipzig, 1870-74); Hertzberg, *Geschichte Griechenlands* (Gotha, 1876-79).

BRA, brä (It. dial., meadow). A city in the province of Cuneo, north Italy, 900 feet above the sea, 31 miles south of Turin (Map: Italy, B 3). It has a church of irregular architecture (barocco), built by Vettone in 1742, and numerous educational and charitable institutions. A trade in silk, wine, cattle, truffles, and leather is carried on. Two miles to the south-east are the ruins of the ancient Pollentia (q.v.). Pop., 1881 (commune), 15,000; 1901, 15,965; 1911, 17,278.

BRABANÇONNE, brä'bän'sün' (Fr. the

Brabantine, i.e., *chanson*, song, from the province of Brabant), LA. The national song of the Belgians, originally sung by the insurgents during the Revolution of September, 1830. A young French player of the name of Jenneval was the author of the song, which was set to music by a singer named Campenhout. Jenneval fell in a combat with the Dutch at Berchem.

BRABANÇONS, bră'ban'sŏn'. A name applied during the later Middle Ages to mercenary soldiers. In 1135 William of Ypres raised bands of mercenaries in Brabant for Stephen of Blois, the claimant of the English crown. The name Brabançons, first applied to the hirelings from Brabant, was used later for mercenaries in general. Because of their deeds of rapine, Brabançons soon became a common name for brigands.

BRABANT, bra-bānt' or bra'bant, *Fr. pion brā'ban'*. A province of Belgium, bounded on the north by the province of Antwerp, on the east by Limburg and Liege, on the south by Namur and Hainaut, and on the west by East Flanders (Map Belgium, C 4). Area, 1258 square miles. The principal towns are Brussels, Hal, Louvain, Aerschot, Diest, Tirlemont, Nivelles, and Wavre. The surface is mostly level and well wooded. It is traversed by the Dyle, Dower, and Senne rivers, and has a well-cultivated soil. The manufacturing industries comprise the production of cotton and woolen goods, ribbons, linen, hats, jewelry, etc. Pop., 1900, 1,263,535, 1905 (est.), 1,392,432, 1910, 1,469,877.

BRABANT (Lat. *Brachbantum*, Ger. *brach*; fallow, unplowed + *Bant*, district). The name formerly given to an important region in the Low Countries, extending from the left bank of the Waal to the sources of the Dyle, and from the Meuse and the plain of Limburg to the lower Scheldt. In the time of Caesar Brabant was inhabited by a mixed race of Germans and Celts, but in the fifth century it came into the possession of the Franks. After the disruption of Charlemagne's Empire it formed part of the Duchy of Lorraine (included in Germany), and after 959 of the Duchy of Lower Lorraine. The Principality of Brabant grew up around the city of Louvain as a nucleus. Beginning with Henry I (1190-1235), the rulers of Brabant bore the title of duke. John I in 1283 annexed Limburg to his dominions. The country possessed a liberal charter, known as the *Joyeuse Entrée*, or "Joyous Entrance" (granted in 1356), which guaranteed extensive rights to the nobles and the towns and restricted the powers of the Duke. In 1430 Brabant came into the possession of the house of Burgundy, and in 1477 passed to the Hapsburgs through the marriage of Mary of Burgundy with the future Emperor Maximilian. The northern part of Brabant participated in the revolt of the Netherlands against the rule of Philip II of Spain and became a part of the independent Dutch Republic. At the close of the Napoleonic wars the whole of Brabant was included in the Kingdom of the Netherlands, and was divided into three provinces. After the Revolution of 1830 the provinces of Antwerp and South Brabant became parts of Belgium. The eldest son of the King of the Belgians bears the title of the Duke of Brabant. Consult DYNTER, *Chronique des Ducs de Brabant* (Brussels, 1854-60), Omond, *Brabant and East Flanders* (London, 1907).

BRABANTIO, bră-bān'shî-ô. The father of

Desdemona in Shakespeare's *Othello*. He is a Venetian noble, vehemently opposed to his daughter's marriage with the Moor.

BRACCARA, BRACARES. See BRAGA.

BRACCIO, brăt'chō, FORTEBRACCI, COUNT OF MONTONE (1368-1424). A celebrated condottiere, born in Perugia of an old patrician family. In his early youth he became a leader of mercenaries and later was the champion of the exiled Perugian nobles. In 1408 he entered the service of Ladislaus, King of Naples, who had designs upon central Italy, and with his command crossed the Apennines, scoured the valley of the Tiber, and took several towns. In June of the same year the people of Perugia offered the dominion of their city to the Neapolitan King, on condition that he should prevent the return of the nobles. He accepted the offer, and Braccio was forced to retire to the marshes. In 1416, however, Braccio secured the possession of his native city, and the banished nobles were restored. In the same year he took Rome, but was soon obliged to evacuate it. Afterward he made terms with Pope Martin V and subsequently accepted from Joanna, Queen of Naples, the command of her land forces and the rank of High Constable of the Kingdom. He entered the Abruzzi, surprised Capua, and relieved Naples. In 1421 he became Prince of Capua, Count of Foggia, and Constable of the Kingdom of Naples. In 1424 he overran Campania and Apulia, took Bari, and advanced into Calabria, but was wounded and captured, while besieging Aquila, and died June 2, 1424. His deeds and those of his contemporary, Piccinino, are commemorated by Lorenzo Spirito, in a poem entitled *L'altro Marte* (Vicenza, 1489).

BRACCIOLINI, brăt'chō-lî-nî, FRANCESCO (1566-1645). An Italian poet, born in Pistoia, and secretary to Cardinal Barberini, afterward Pope Urban VIII. His *Croce racquistata* (1611) is one of the best of the numberless Italian imitations of Tasso's epic, but his fame rests on his burlesque poem *Lo scherzo degli dei* (1618-1626), of which the ostensible purpose was to satirize paganism in itself and in the use made of it by contemporary writers. The satire, however, turns out to be largely incidental to a much broader comic sense, expressing itself through all the motives common at the time, and in a notably chastened style which makes the work a classic. Consult M. Babì, *La vita e le opere di F. Bracciolini* (Florence, 1897), and Belloni, *Gli epigrammi della Gerusalemme liberata* (Padua, 1893). Bracciolini was a prolific cultivator of dramatic and lyric poetry as well.

BRACCIOLINI, POGGIO. See POGGIO BRACCIOLINI, GIOVANNI FRANCESCO.

BRACCIO NUOVO, nrwô'vô. An imposing vaulted hall in the Vatican, built in 1821, containing about 120 works of ancient sculpture, among them the "Apocryphomenos," the "Augustus," the "Nile Group," and the "Athlete."

BRACE (OF *brace*, *brasse*, the two arms, embrace, from Lat. *Brachia*, pl. of *brachium*, arm). A beam or bar in a roof or bridge truss placed in an inclined position and serving to hold together the principal members, generally any timber used to stiffen a framed structure. The contrivance or tool for holding a bit, used by carpenters for boring, is also called a brace (See BRIDGE, ROOF, BORING TOOLS AND MACHINERY). Braces on shipboard are ropes attached to the yardarms and employed to shift

the sails in a horizontal direction round the masts, so as to receive advantageously the wind that may be blowing at any particular moment. To *brace in* is to bring the forward yardarm farther aft, i.e., to lay the yard more nearly square; to *brace up* is the reverse of this; to *brace about* is to swing the yard from being sharp up (i.e., as far forward as possible) on one tack to sharp up on the other. In construction of all kinds the term "brace" signifies a form of prop which supports by resistance to compression as opposed to a strut, tie, or hanger, which supports by resistance to tension.

BRACE, CHARLES LORING (1826-90). An American philanthropic author. He was born at Litchfield, Conn., June 19, 1826, graduated at Yale, studied in the Yale and in the Union Theological seminaries, but never had charge of any church. In 1850 he made a pedestrian tour in Great Britain, and the next year went to Hungary. Afterward he studied the school systems of Switzerland, England, and other countries. On his return in 1852 he became associated in the early operations of the "New York Children's Aid Society," and as secretary of that society did a great work among newsboys and in riding New York City of unruly children. He became widely known as a philanthropist. He died at Campfer, in the Engadine, Switzerland, Aug. 11, 1890. He visited Europe often, and the result of his observations is found in *Hungary in 1851* (New York, 1852); *Home Life in Germany* (1853); *Norse Folks* (1857); *Races of the Old World* (1863), etc. He also published: *The New West* (1868); *Short Sermons to Newsboys* (1861); *Dangerous Classes of New York* (1872); *Gesta Christi* (1883); *The Unknown God* (1889). Consult his life, ed. by his daughter (New York, 1904).

BRACE, CHARLES LORING (1855-). An American philanthropist, son of the preceding. He was born in Dobbs Ferry, N. Y., graduated at Sheffield Scientific School, Yale University, in 1876, and worked as a construction engineer on railways in the Middle West until 1890. Then, upon the death of his father, who had founded the Children's Aid Society, he became the organization's secretary. He is author of many pamphlets, papers, and reports on the saving of children.

BRACE, DE WITT BRISTOL (1859-1905). An American physicist born in Wilson, N. Y. He graduated at the Boston University in 1881, received the degree of M.A. there a year afterward, studied at Johns Hopkins University from 1881 to 1883, and received the degree of Ph.D. from the University of Berlin in 1885. He was appointed acting assistant professor at the University of Michigan in 1887, and became professor of physics at the University of Nebraska in 1888. He has made a special study of radiation and optics and has published *Laws of Radiation and Absorption* (1901).

BRACEBRIDGE. A town in Muskoka district, province of Ontario, Canada, situated at the head of navigation of the Muskoka River, 125 miles north of Toronto, and on the Grand Trunk Railway (Map: Ontario, E 3). It has woolen, flour, saw, shingle, and planing mills, tanneries, and a linen factory. It is in a lumber-producing district and is a popular summer resort. Pop., 1901, 2479; 1911, 2776.

BRACEBRIDGE HALL, or **THE HUMOR-**

ISTS. The title of a volume of essays by Washington Irving (1822). Bracebridge Hall was taken as a type of the English country seat. It appeared under the name of "Geoffrey Crayon, Gent."

BRACE/GIR'DLE, ANNE (c.1674-1748). An English actress. She was said to have been brought up by Mr. and Mrs. Betterton and to have appeared as a child in *The Orphan* at Dorset Garden, but her early history is not well known. She took the part of Lucia in Shadwell's *Squire of Alsatia* at the Theatre Royal in 1688 and from that time is frequently on record. In 1693 she played Araminta in Congreve's *Old Bachelor*. In 1695 she joined Betterton, Mrs. Barry, and the other seceders to Lincoln's Inn Fields, and played Angelica in *Love for Love*. She was Belinda in Vanbrugh's *Provoked Wife*, and the same year (1697) Almeria in Congreve's *Mourning Bride*. Among her characters were several tragic parts, but she was thought to be best in comedy. Her personal attractions were famous. Cibber says of her: "Never was any woman in such general favor of her speculators, which to the last scene of her dramatic life she maintained by not being unguarded in her private character." The last curious phrase has been much quoted and met with some debate. Mrs. Bracegirdle's reputation for a virtue then not too common upon the stage seems, however, to have been well sustained. She was the innocent cause of the death of the actor William Mountfort, who was killed by a jealous Captain Hill and Lord Mohun. Cibber adds, "Scarce an audience saw her that were less than half of them lovers, without a suspected favorite among them." It was half believed, nevertheless, that she was privately married to Congreve. A purse of £800 was once given her by Lord Halifax and some friends as a testimonial to her character. She was noted besides for her charity to the poor. Her retirement from the stage, in 1707, was owing to jealousy of the popularity of Anne Oldfield, and she played thereafter but once, at Betterton's benefit in 1709. Consult: Genest, *History of the Stage* (Bath, 1832); Egerton, *Life of Ann Oldfield* (London, 1731); Doran, *Annals of the Stage*, ed. Lowe (London, 1888); Russell, *Representative Actors* (London, 1875); Baker, *English Actors* (New York, 1879); and Cibber, *Apology*, chap. v, ed. Bellchambers (London, 1822).

BRACE/LET (Fr. armllet, from *bras*, hand, Lat. *brachium*, arm, Eng. *brace*). An ornament worn on the arm, generally at the wrist. Bracelets and armllets have been used by every nation, both savage and civilized, from the earliest periods to our own. They are frequently mentioned in Genesis, as worn both by men (xxxviii. 18) and by women (xxiv. 30); as worn by both the Hebrews and the surrounding nations they appear in Num. xxxi. 50. Similar ornaments were worn round the ankles, but they are stigmatized by Isaiah as marks of luxury (iii. 16). The Medes and the Persians were remarkable, even among Asiatics, for their love of ornaments of this class. They wore not only bracelets and armllets, but earrings, collars, and necklaces, which often consisted of strings of valuable pearls or were enriched with other jewels. These ornaments were used to indicate the rank of the wearer and this use has continued to be made of them in the East down to the present day. In Europe bracelets and armllets were worn by both

the classical nations and the barbarians from the earliest times. The Gauls wore them, and the Sabines, in the legend of Tarpeia (qv), had ponderous golden armlets on the left arm. Armlets have been found at Tiou, Mycene, and in the early Italian graves. They were worn on both the lower and the upper arm and are frequently found in pairs. In historical times it was a mark of effeminacy for men to wear bracelets, but they are very frequently seen on women in works of art, and very many have been found in tombs. Some of these are exceedingly beautiful specimens of the goldsmith's work. The favorite form seems to have been a spiral passing several times around the arm and frequently made to resemble a serpent. We also find simple rings, often open, with the ends in the form of animals' heads, sphinxes, etc. Almost all modern forms can be found among the Greek and the Etruscan jewelry. These armlets were frequently arranged to contain amulets. Among the Romans silver armlets (*armille*) were given to soldiers or centurions as a mark of distinction.

BRACHELLI, bra-kél'le. HUGO FRANZ VON (1834-92). An Austrian statistician. He was born in Brunn and studied at the University of Vienna. He published the important statistical work *Die Staaten Europas* (1853, 5th ed., 1907). He was appointed director of the statistical department of the Austrian Ministry of Commerce in 1872. Among his more important works are *Die deutsche Staatenkunde* (1850), *Statistische Skizzen der Europäischen Staaten ausser Oesterreich* (7th ed., 1892), *der Oesterreichisch-ungarischen Monarchie* (13th ed., 1892).

BRACHET, bra-shé', AUGUSTE (1845-98). A French philologist. He was born in Tons and studied under Diez and Littré. In 1870 he was appointed professor of Romance philology at the Ecole des Hautes Etudes, Paris, and from 1872 to 1874 he was examiner of German in the Ecole Polytechnique. His *Grammaire historique de la langue française* (1867), which was the first work of its kind, enjoyed for many years a very great popularity. More than 30 editions of it appeared, notwithstanding the fact that the author refused to the very last to revise it in accord with the progress of philology. It was translated into English by Kitchin (Oxford, 1869), and was adopted as a textbook in all the leading English and American universities. His *Dictionnaire étymologique de la langue française* (Paris, 1870) was intended to be a companion volume to the grammar. With the cooperation of Gaston Paris and Moisl-Fatio, he translated into French the *Grammaire des langues romanes* of Diez (1873-76). Brachet was more successful as a journalist. His *L'Italie qu'on voit et l'Italie qu'on ne voit pas* (1881) was one of several publications in which he endeavored to show that the education of the youth of Italy was everywhere influenced by a pronounced antagonism to France and the desire of a closer alliance with Germany. This pamphlet drew a reply from the Italian Premier Crispi, who, in a long letter (*L'onorevole Crispi al Signor Brachet*, Rome, 1881), denied the truth of his assertions. Brachet replied with a detailed refutation in another pamphlet, *Al Misogallo Signor Crispi* (1882), attacking at the same time the Italian Ambassador Nigra, who had taken part in the quarrel (*Réponse a S. E. M. Nigra*, Paris, 1882).

BRACHIAL (brá'ki-al) ARTERY (Lat. *brachialis*, belonging to the arm, from *brachium*, arm). The artery between the armpit and the elbow, which is the continuation down-

BRACHIAL ARTERY

ward of the axillary artery. The brachial artery at first runs along the inner side of the arm, just behind the inner margin of the biceps muscle and behind the great median nerve. Here it may be pressed against the bone, in cases of bleeding from any point below. Then it passes across to the front and outer side of the arm. In its course the brachial artery gives off (1) the superior profunda branch, which winds round the back of the arm bone and reappears on the outer side, where it joins some twigs coming up from the radial artery, (2) an artery which enters the bone to supply its medullary membrane, (3) inferior profunda, which, running down behind the internal condyle of the humerus, joins branches coming from the ulnar artery, (4) a short branch, the anastomotica magna, which breaks up into numerous branches, anastomosing around the elbow.

BRACHIOPODA, brák'f-óp'ô-dá (Gk. arm-footed, from *brachion*, arm + *pous*, foot). A class of peculiar animals, having bivalve shells, but differing in important points from the vast majority of recent mollusks with bivalve shells. The mantle or pallium (see MOLLUSK) in the Brachiopods consists of two broad expansions or lobes, covered by the two valves of the shell, which are dorsal and ventral, and inclosing all the other soft parts of the animal, while the chief function of these folds is unquestionably the formation of the two-shell valves, it is possible that they are supplied with blood lacuna or vessels, and may serve as the principal organs of respiration. The circulatory system is not satisfactorily known, but there is probably a vascular system present, with a heart placed above the intestine. The nervous system is weakly developed, but includes a small brain and a larger infrapharyngeal ganglion, with two principal trunks running backward from it. There are no special sensory organs of any kind. The organs by which food is procured are also remarkable—two long arms arising from the sides of the mouth, and disposed wholly or partly in spiral curves, when not extended to seek or seize prey. These arms are usually furnished with numerous vibratory filaments, which are supposed not only to aid in the capture of prey, but in the maintenance of the current necessary for respiration. The arms are often supported by a special

REPRESENTATIVE BRACHIOPODA

1. *Orania Bordeni*. 2. *Spirifer cameratus*. 3. *Bilobites biloba*. 4. *Tropidoleptus occidentis*. 5. *Pentamerus oblongus*. 6. *Uncites gryphus*. 7. *Derbya Bennetti*. 8. *Orthis tricenaria*. 9. *Athyris spiriferoides*. 10. *Orthis pectinella* (Interior). 11. *Rhipidomella Michelina*. 12. *Stropheodonta demissa*. 13. *Camarotoechia congregata*.

calcareous skeleton, attached to the dorsal valve.

Excretion takes place by means of nephridia, of which one or two pairs are present; these also serve as ducts for the transmission of the sexual products. They open into the mantle cavity on each side of the mouth. The Brachio-

ANATOMY OF BRACHIOPODA.

Structure of *Terebratula*.—A, the shell viewed from behind, showing the dorsal valve, and the perforated summit of the ventral valve above it. B, inner view of the dorsal valve, showing the shell loop (C) which supports the spiral arms. C, inner view of the ventral valve, showing the foramen or aperture (F) in the beak, through which (D) the muscular stalk of attachment passes. D, longitudinal and vertical section of the animal, showing the spiral arm (a), the stomach (s), and the liver (l). At (t) is the opening in the beak, with the stalk of attachment (p) passing through it. (After Davidson and Owen.)

oda are attached to solid bodies either by a footstalk or by one of the valves of the shell. When the stalk is present, it emerges either between the valves or through a hole in the posterior upward bulging of the larger ventral valve. The Brachiopoda are most notable because of the fact that in the earliest geological times they were a dominant type; but since the close of the Paleozoic Age they have been steadily decreasing in number. More than 4000 species are known, but more than 95 per cent are extinct and exist only as fossils. Most of the living Brachiopods are small, less than an inch across, but some of the extinct forms were 6 inches across. All living species are marine, and there is every reason to believe the same is true of the extinct species. Existing species are found in water of moderate depth, sometimes down to 250 fathoms. They are generally grouped in two orders: the Articulata, or Testicardines, in which the shell-valves are hinged, and the Inarticulata, or Ecardines, without hinge. Examples of Brachiopods are shown on the plate: 1, *Crania bordeni*; 2, *Spirifer cameratus*; 3, *Bilobites biloba*; 4, *Trochileptus occidentalis*; 5, *Pentamerus oblongus*; 6, *Unio gryphus*; 7, *Derbya benettii*; 8, *Orthis trocarnaria*; 9, *Athyria spiriferoides*; 10, *Orthis pectinella* (interior); 11, *Rhipidomella michelini*; 12, *Strophodontia demissa*; 13, *Cammarotoechia congregata*.

BRACHIOSAURUS, brák'i-ó-sa'rus. A dinosaur of extraordinary proportions, exceeding in size even the massive Brontosaurus (q.v.), which lived in Jurassic times. Parts of an incomplete skeleton found in western Colorado show that the animal possessed very long limbs, of which the front ones were especially long and heavy, in-

dicated that it probably obtained its food by browsing on the foliage of trees which it was able to reach without rearing upon its hind legs, as did some members of the family. It possessed a long and flexible neck and in other respects may have resembled the Brontosaurus.

BRACHIOSPONGIA, brák'i-ó-spón'jî-á (Gk. *brachion*, brachion, arm + *spongia*, sponge, sponge). A curious genus of hexactinellid sponges. This sponge has a form somewhat like that of the earth-star puffball (*Geaster*) and consists of a central depressed hollow portion from which radiate several cylindrical arms that are bent downward towards the ocean floor upon which the sponge lived. Into these arms extend prolongations of the central gastral cavity. The aperture of the gastral cavity is large and often elevated above the plane of the arms. These sponges have been found chiefly in the Ordovician rocks of Franklin Co., Ky., where they occur as hard, stony masses. The stony nature is due in part to a compact skeleton of delicate siliceous spicules that gave rigidity to the sponge mass when alive, and also to mineral matter that has been deposited in the cavities of the skeleton during the progress of petrification. Consult Beecher, "Brachiospongia," *Memoirs of the Peabody Museum of Yale University*, vol. ii, pt. i (New Haven, 1889). See also Sponges.

BRACHISTOCERONE, brá-kis'tó-krón (Gk. *brachistos*, brachistos, shortest + *chronos*, chronos, time). The curve of quickest descent. See CYCLOID.

BRACHT, brákt, EUGEN FELIX PROSPER (1842-). A German landscape painter, born at Morges, on Lake Geneva, Switzerland. He studied chiefly at Karlsruhe and Düsseldorf, under H. Gude. In 1882 he was appointed an instructor in the Berlin Academy and in 1901 professor at the Dresden Academy. He first gained recognition by his landscapes of the Lüneburg Heath and the shores of the Baltic, showing a very dramatic conception of nature. "A Stormy Day at Rügen" and "The Giant's Grave in Humling" are among the best works of this early period. He later made a journey to the East, and his glowing landscapes of Egypt, Syria, and Palestine added greatly to his reputation. "Mount Sinai" and the "Brook Kidron," in the Museum of Königsberg, "Nightfall on the Dead Sea," in the National Gallery, Berlin, are some of the best examples of these. Other well-known works of a later period are "Hannibal's Grave," "The Tomb of Cecil Rhodes," and "The Three Towers of the Gauerthal." Practically all German museums possess specimens of Bracht's art. He also painted panoramas, among others the "Battle of Chattanooga," for the United States. Consult Osborn, *Eugen Bracht* (Bielefeld, 1909).

BRACHVOGEL, brák'fó-gel, ALBERT EMIL (1824-78). A German dramatist and writer of fiction, born in Breslau. He studied engraving and modeling, but having subsequently turned author, wrote several dramas and a large number of long-winded works of historical fiction. The dramas include *Narriss* (1857; 6th ed., 1882), translated into several European languages, on which his reputation rests. Among his novels, which are rather sensational and not artistically well rounded, may be mentioned *Friedmann Bach* (1858), his best; *Benoni* (3 vols., 1860); *Beaumarchais* (4 vols., 1865); *Der Deutsche Michael* (1868); *Glanccarty* (4 vols., 1872). His *Gesammelten Romane, Novel-*

Ien and Dramen (10 vols, 1870-83), were edited by Max Ring. Consult Mittelemann, *Albert Emil Brachvogel und seine Dramen* (Leipzig, 1910).

BRACHYLOGUS, bra-kil'ō-gūs (Gk. βραχύς, *brachys*, short + λόγος, *logos*, word). A work containing a systematic exposition of the later Roman law, compiled probably in the twelfth century, though some assign it to the reign of Justinian. Its authorship is unknown. The earliest extant edition was published at Lyons in 1549. It is based mainly on the Institutes of Justinian, though it is drawn largely from the Digest and other parts of the Corpus Juris.

BRACHYURA, brak'i-ū'ra. See CRUSTACEA, CRAB.

BRACKENBURY, Rt Hon Sir Henry (1837-1914). An English soldier. He was born in Lincolnshire, England, and in 1856 joined the Royal Artillery. He served in the Central Indian campaign (1857-58) and in the Ashanti campaign (1873-74), and was chief of staff during the Zulu War (1879-80). Subsequently he was military attaché at Paris (1881-82), accompanied the Nile Expeditionary force as deputy adjutant general (1884), and, after the death of General Earle, took command of the River Column. For his services he was made major general (1885). He became lieutenant general in 1888, colonel commandant of the Royal army in 1897, general in 1901, and was director general of ordnance at the War Office in 1899-1904, when he retired. Sir Henry's publications include *Fanti and Ashanti* (1873), *Narrative of the Ashantee War* (2 vols, 1874), *The River Column* (1885), *Some Memories of my Spare Time* (1900).

BRACKENRIDGE. A borough in Allegheny Co., Pa., 23 miles from Pittsburgh, on the Pennsylvania Railroad, and on the Allegheny River. It has deposits of coal, oil, and natural gas, and includes among its industrial establishments glass factories and steel mills. Pop., 1910, 3421.

BRACKENRIDGE, HENRY MARIE (1786-1871). An American lawyer and author, son of Hugh Henry Brackenridge (q.v.). He was born in Pennsylvania, practiced law in Maryland, and in 1812 became district judge of Louisiana, in which position he was useful to the government in the War of 1812, of which he wrote a history. He advocated the acknowledgment of the independence of the South American states, and his pamphlet on the subject received an official answer from the Spanish Minister at Washington. Subsequently he was commissioner to the new republics, and published *A Voyage to South America* (1818). He was judge of the western district of Florida for 10 years and then removed to Pittsburgh, Pa. In 1841 he was commissioner under the treaty with Mexico. Besides many essays on various subjects, he published *Views of Louisiana in 1810* (1811), a part of which was reprinted in 1904 as *Journal of a Voyage up the River Missouri in 1811*, *Recollections of Persons and Places in the West* (1834), *History of the Late War between the United States and Great Britain* (6th ed., 1846), and a *History of the Western Insurrection* (1859), written in vindication of his father.

BRACKENRIDGE, HUGH HENRY (1748-1816). An American lawyer, politician, Revolutionary chaplain, poet, satirist, and miscellaneous writer, born at Campbellton, Scotland. Brackenridge was graduated from Princeton in

1771, a classmate of James Madison. Part of the graduating exercises of that year was a poetical dialogue, *The Rising Glory of America*, written by Brackenridge in collaboration with Philip Freneau (q.v.) and published in 1772. For five years he taught at Princeton and in Maryland, writing for his pupils a drama, *Bunker Hill*, published in 1776, in which year he went to Philadelphia as editor of the newly founded *United States Magazine*. Brackenridge, who had studied divinity, then became chaplain in the Revolutionary army, though never regularly ordained. Six of his *Camp Sermons* were published. He soon left the army, however, and, after studying law at Annapolis, was admitted to the bar, moved to Pittsburgh, became prominent politically, and in 1786 was sent to the Legislature. He was active as a mediator in the Whisky Insurrection (1794), and wrote, as a defense of his action, *Incidents of the Insurrection in Western Pennsylvania* (1795). In 1799 he was made judge of the State Supreme Court. The best known of his publications, and the only one of present literary interest, is a political prose satire, *Modern Chivalry, or the Adventures of Captain Farrago and Teague O'Regan, his Servant* (1796-1806). Brackenridge died at Carlisle, Pa., June 25, 1816. Consult Trent, *American Literature* (New York, 1903).

BRACKET (ME *bragget*, Fr *biaquette*, dimin of Lat **braca*, sing of *bracca*, breeches). 1 A support projecting from a wall, pier, or column, especially, such a support of approximately triangular form, this being the shape best adapted to the various strains exerted. A framed bracket has for its essential parts a horizontal top piece, a vertical wall piece and an oblique brace. If the top and brace are securely anchored, the wall piece may be omitted. Brackets, whether of stone, metal, or wood, are often of highly ornate design. In India framed brackets of stone are found, but stone brackets are usually of one piece and are called, according to their style and shape, corbels, modillions, consoles, and cantilevers. The term "corbel" is usually restricted to stone supports having slight projection in proportion to their height. 2 A projecting, often pivoted arm carrying a gaslight or electric light. See CANTILEVER, CONSOLE, CORBEL, MODILLION.

BRACKET FUNGI. Certain fungi taking the form of brackets on trees and stumps. They belong to the group Basidiomycetes (q.v.).

BRACKETT, ANNA CALLENDER (1830-1911). An American educator and author, born in Boston, Mass. She graduated at Framingham (Mass.) Normal School in 1836, and thereafter taught in several schools and held executive positions, such as the principalship of the St. Louis City Normal School. The school for girls which she established in New York City in 1872 was the first girls' school in the State to require Latin for all students and to place German in the regular course of study. She had been associated in St. Louis with W. T. Harris and Henry C. Brockmeyer in their Philosophical Society, and in 1886 she published a translation of Karl Rosenkranz's *Philosophy of Education*. She also wrote poetry, contributed to the *New York Nation*, collected a *Treasure Book of Verse* (1876), edited the valuable series of essays *Education of American Girls* (1874) and *Women and the Higher Education* (1893), and wrote *The Technique of Rest* (1892).

BRACKETT, CYRUS FOGG (1833-). An

American physicist, born at Parsonsfield, Me. He was educated at Bowdoin College, where he served as instructor in chemistry in 1863 and as professor of chemistry from 1864 to 1873. From then until 1908, when he became professor emeritus, he was professor of physics at Princeton University. He published *Physics* in 1889.

BRACKETTVILLE. The county seat of Kinney Co., Tex., 140 miles west of San Antonio (Map: Texas, B 5). It has stock-raising interests and is the seat of a United States military post, Fort Clark, established in 1852. The post was once of much importance in repressing Indian and Mexican raids from beyond the Rio Grande. Pop., 1910, 1750.

BRACKS. See **BRAXY**.

BRACQ, JEAN CHARLEMAGNE (1853-). An American publicist and college professor, born at Cambrai, France. In 1871 he came to the United States, graduated from McGill University, Montreal, in 1881, and later studied at the Newton Theological Institution, in Edinburgh, and in Paris. After serving as secretary of the American McAll Association, Philadelphia, in 1885-91, he became associate professor (1891) and then professor (1892) of Romance languages, at Vassar. From 1896 to 1903 he was editor of the *Huguenot Quarterly*. His paper, *French Rights in Newfoundland*, read before the Academy of Moral and Political Sciences in Paris, was used as the historical basis for settling the Newfoundland dispute. Besides writing much on questions of French Protestantism, Anglo-French relations, French colonial expansion, and the relation of the French government to the Church, he published *France under the Republic* (1910).

BRACQUEMONT, brák'môn', JOSEPH AUGUSTE (1833-). A French painter, etcher, and designer for ceramics. He was born in Paris and was a pupil of Guichard. He began to exhibit as a painter in the Salon of 1852, but won his reputation chiefly by his original etchings and his reproductions of the works of the great masters. He is especially successful in depicting animal life and in portraits, among which are many of noted artists and writers, and also distinguished himself as an illustrator. His etching work is represented by over 1000 plates, including a number of excellent lithographs. About 1867 he introduced successfully a new mode of decoration on china, in which the Japanese influence is predominant, and in 1872 became connected with the painting department of the porcelain factory at Sèvres. He soon afterwards established a studio for ceramic decoration on the outskirts of Paris and did a great deal of work for a Limoges factory.

BRAC'T (Lat. *bractea*, a thin plate of metal, gold leaf). Usually a leaf associated with a flower cluster (inflorescence), which is usually smaller than the ordinary leaves and often more or less modified in structure. In certain flower clusters the bracts are distributed along the axis as are the ordinary leaves. In other cases, as among the Compositæ, the bracts form a rosette beneath the cluster of flowers. Sometimes the term "bract" is applied to any kind of reduced leaf, as in buds, bulbs, etc., but more commonly the term "scale" is used in such cases. See **INFLORESCENCE**.

BRAC'TON, or BRATTON, HENRY DE (thirteenth century). An English ecclesiastic, distinguished as a judge and as the author of the

first comprehensive treatise on English law. He was born at Bretton-Clovelly, in Devonshire, and studied at Oxford, where he took the degree of doctor of laws, and where he is supposed to have lectured on the canon law. He became an itinerant judge in 1245 and shortly thereafter a judge of the King's Court. His ecclesiastical and judicial preferment went hand in hand. In 1263 he was Archdeacon of Barnstable and Chancellor of Exeter Cathedral, and in 1265 he is said to have become chief justiciary of England under Henry III. Of his history subsequently to 1267 we know nothing. His fame rests on his great work on the laws of England, *De Legibus et Consuetudinibus Angliæ* (on the Statute and Common Law of England), which has been characterized as "the crown and flower of English mediæval jurisprudence" (Pollock and Maitland, *History of English Law*). It is a systematic treatise, written in Latin, on a large and comprehensive plan, not wholly completed, drawing its form largely from the Roman law, but deriving its substance almost entirely from the precedents of the English law courts. The belief, long entertained, that the book is a composite of Roman and English law, that it represents an attempt to refine and improve the common law by introducing the conceptions of the civil law, has been disproved by recent investigations of the plea rolls and other authorities upon which the author relied. The work was an immediate success. Some 50 manuscripts of it have come down to us, and in that age of legal activity it became the model of numerous other treatises, some of which, like those of Fleta and Britton, have also survived. But Bracton had no successor until, 500 years after his death, Blackstone gave his *Commentaries* to the world. The earliest edition of Bracton's *De Legibus* is the folio edition of 1569; the best edition is the one edited by Sir Travers Twiss, and issued in 1879-83, with an English translation, under the authority of the Lords Commissioners of the Treasury, and under the direction of the Master of the Rolls. Certain British Museum manuscripts containing the record of some 2000 cases were discovered about 1884 by Prof. Paul Vinogradoff to have been compiled by Bracton as a "Note Book," and were edited by F. W. Maitland for publication. Consult: *Bracton's Note Book*, edited by Maitland (London, 1887); *Select Passages from Bracton and Azo*, edited for the Selden Society by Maitland (London, 1895); Pollock and Maitland, *History of English Law* (2d ed., Cambridge, Eng., and Boston, 1889); Scrutton, *Influence of the Roman Law on the Law of England* (Cambridge, Eng., 1885).

BRADAMANT. The daughter of Amon and Beatrice and the sweetheart of Roger the Moor. The latter becomes a Christian on her making this act a condition of their marriage. Bradamant, known as the Virgin Knight, had white armor and an irresistible spear. She appears in Boiardo's *Orlando Innamorato* and Ariosto's *Orlando Furioso*. There is a play with the title *Bradamante*, a tragi-comedy by Robert Carnier (1580); a tragedy by La Calprenède (1636); a tragedy by Thomas Corneille (1695), besides several others.

BRADBURY, JOHN BUCKLEY (1841-). An English physician and author. He was born at Saddleworth, Yorkshire, and was educated at King's College, London, and at Cambridge. He became physician to Addenbrooke's Hospital,

Cambridge, in 1869 Bradshaw lecturer at the Royal College of Physicians, London, in 1895, Croonian lecturer to that body in 1899, and examiner in materia medica in the University of Oxford His publications include *On Vertigo Its Causes, Importance as a Symptom, and Treatment* (1870), *Inaugural Lecture on Pharmacology* (1894), *On Some New Vaso Dilators* (1895), *On Some Points Connected with Sleep, Sleeplessness, and Hypnotics* (1899)

BRADDOCK A borough in Allegheny Co, Pa., 10 miles east of Pittsburgh, on the Monongahela River, and on the Pennsylvania, the Baltimore and Ohio, and the Pittsburgh and Lake Erie railroads (Map Pennsylvania, B 8) It has extensive manufactures of steel, wire, ferromanganese, pig iron, steel rails, cement, machine tools, and plaster Braddock has the first Carnegie library established in America, a hospital, Federal building, and Kenneywood Park Settled probably about 1795 on the site of Braddock's defeat in 1755, Braddock was incorporated in 1867 The borough is governed by a burgess, holding office for three years, and a council in whose power rests the appointment of the important officials of the city The water works are owned and operated by the borough Pop, 1890, 8561, 1900, 15,654, 1910, 10,357

BRADDOCK, EDWARD (1695-1755) A British general, who in 1755 led an expedition against Fort Du Quesne, in the French and Indian War (qv) With a force of 1200 picked men, regulars and provincials, he reached the Monongahela, a branch of the Ohio, on July 8. Disregarding the advice of Franklin and Washington, of the probability of a surprise, he advanced on July 9 in confident security until, when seven miles from the fort, the force was ambushed by Indians and attacked simultaneously in front by the French Complete rout ensued, as the British were cut to pieces, until the survivors, less than half of the command, were led to safety by Colonel Washington, one of the General's aids Braddock himself, while striving to re-form his men, was mortally wounded and died a few days later at Great Meadows, 50 miles away, whither he had been carried after the defeat Consult *The History of the Expedition against Fort Du Quesne in 1755, Edited from the Original Manuscripts*, by Winthrop Sargent (Philadelphia, 1856), and Parkman, *Montcalm and Wolfe* (Boston, 1884)

BRAD'DON, MARY ELIZABETH (Mrs Maxwell) (1837-) An English novelist, born in London In 1860 she wrote a comedietta called *The Loves of Arcadia*, and the following year published *Caribals and Other Poems* Her first great success, however, came with the publication, in 1862, of *Lady Audley's Secret* This has since been extended by the appearance of, among other books, *John Marchmont's Legacy* (1863), *The Doctor's Wife* (1864), *Only a Clod* (1865), *The Trail of the Serpent* (1866), *Run to Earth* (1868), *Dead Sea Fruit* (1868), *The Lovels of Arden* (1871), *Weavers and Weft* (1877), *One Life, One Love* (1890), *Under Love's Rule* (1897), *In High Places* (1898), *His Darling Son* (1899), *The Conflict* (1903), *The Rose of Life* (1905), *The Green Curtain* (1911), *Miranda* (1913) Miss Braddon in 1863 was regarded as a remarkably sensational and almost "improper" writer—an opinion that was quite unjustified One of her novels, *The Doctor's Wife*, closely resembles Flaubert's masterpiece of mordant realism, *Madame Bovary*

She was married to John Maxwell, a London publisher, in 1874

BRADFORD (AS *brād*, broad + *ford*, ford). An important manufacturing city in the West Riding of Yorkshire, England, on a tributary of the Aire, 8 miles west of Leeds (Map England, E 3) Among the notable public buildings are the church of St Peter, dating from 1485, the Fexchange (1867), the Town Hall, Piece Hall, St George's Hall (a concert hall seating some 4000 people, built in 1853), and the Cartwright Memorial Hall (1904), erected in memory of Dr Edmund Cartwright (qv), inventor of the power loom and combing machine Bradford has been a parliamentary borough since 1832 and returns three members to Parliament It was made a city in 1897 The city's affairs are administered by a lord mayor (since 1907), a municipal council of 63, and a board of aldermen of 21 members Bradford is one of the most highly municipalized cities in Great Britain The water, gas, and electric light works, the street and suburban railways, markets, slaughterhouses, baths, sterilized milk depot, filtering plants, cemeteries, etc., are all owned and operated by the corporation The municipal railway, opened in 1907, extends into the Nidd valley, the chief source of the city's water supply The net receipts from this service in 1909-10 amounted to nearly \$445,000 The water works represented (in 1911) an outlay of more than \$18,000,000, and their operation in 1909-10 earned a net surplus of \$75,000 The electric supply plants represented a capital outlay of about \$3,500,000, and their operation in the same period earned net receipts of about \$300,000 Among other municipal institutions are public markets, and a "conditioning house" for testing the quality of raw wool and woolen goods, certificates as to their quality being issued

Bradford has seven parks and numerous small recreation grounds It has an excellent public-school system, the United Yorkshire Independent College (1888), a Technical College (opened in 1882 and under the corporation since 1889), a mechanics' institute (founded in 1832, and housed in the fine Mechanics' Hall since 1871), 24 public circulating libraries, and an art museum Among its benevolent and charitable institutions are several hospitals, including one for fever patients, a blind and a deaf-and-dumb asylum, and an orphan asylum Bradford is the chief seat in England of the spinning and weaving of worsted yarn and the great mart for the long wools used in worsted fabrics It also manufactures woollens, silk, cotton, velvet, and plush Bradford is the seat of a United States consulate, in 1912 its exports to the United States amounted to \$14,924,392 in value In the vicinity coal and iron are mined, and the city has several extensive iron foundries Bradford is on four railway lines and on the Bradford Canal Its street railways are owned by the corporation, but are operated by private companies, with the exception of a short section of trolley line operated by the city Baptists, Independents, and Wesleyans have colleges near the town The first English temperance society was established at Bradford in 1837 The Romans seem to have worked iron mines here, Roman coins having been found in foundry refuse near the town The manor of Bradford, after the Conquest, was held in turn by the De Lacey, the house of Lancaster, the crown, and the Corporation of

London. During the Civil War the citizens of Bradford sided with Parliament and twice defended the town successfully against the Royalists, but were forced to surrender to the Earl of Newcastle in 1643. Sir Titus Salt (q.v.), the founder of the famous manufacturing village near Shipley, called Saltaire, was a merchant of Bradford and at one time its mayor. Pop., 1891, 265,728; 1901, 279,809; 1911, 288,505. Consult Ogden, *Bradford* (London, 1910).

BRADFORD. A city in McKean Co., Pa., 78 miles south of Buffalo, N. Y.; on the Buffalo, Rochester, and Pittsburgh, the Pennsylvania, and the Erie railroads (Map: Pennsylvania, D 2). The Kinzua Bridge, 14 miles distant, is 300 feet high and 2100 feet long. Noteworthy features of the city are its large, well-equipped hospital, the opera house, driving park, an historical society, and the public library. Bradford is in a petroleum and natural-gas region; has a large trade in oil, wood acid, alkalis, and gasoline; and extensive manufactures of refined oil, oil-well tools, building and paving brick, tile, vacuum cleaners, silks, furniture, boilers, gas engines, and air compressors. There are also large tile and cutlery works. Settled in 1823, Bradford was chartered as a city in 1879. The commission form of government was adopted in 1914. The city owns and operates its water works and is supplied with natural gas in abundance for fuel and lighting purposes. Pop., 1900, 15,029; 1910, 14,544.

BRADFORD, ALDEN (1765-1843). An American writer, born in Duxbury, Mass. He graduated at Harvard in 1786; was minister of a Congregational church in Wiscasset, Me. (1793-1801); was Secretary of State for Massachusetts (1812-24), and, in 1826, edited the *Boston Gazette*. Among his publications are: *Speeches of the Governors of Massachusetts from 1765 to 1775* (1818); *A History of Massachusetts, from 1764 to 1820* (1822-29); *Life of Jonathan Mayhew* (1838); *History of Federal Government* (1840); *New England Chronology, 1497-1800* (1843).

BRADFORD, AMORY HOWE (1846-1911). An American clergyman. He was born at Granby, N. Y., graduated in 1867 at Hamilton College, and in 1870 at Andover Theological Seminary, and in the latter year became pastor of the First Congregational Church, Montclair, N. J. With the Rev. C. F. Deems he organized the American Institute of Christian Philosophy. He founded the Whittier House Social Settlement of Jersey City and was a founder of the Congregational Club of New York. In 1896 he was a member of the deputation sent by the American Board of Foreign Missions to investigate mission work in Japan. In 1904 he was chosen president of the American Missionary Association. He became an editor of the *Outlook*, of New York, and published *The Pilgrim in Old England* (1893); *The Growing Revelation* (1897); *Heredity and Christian Problems* (1895); *The Age of Faith* (1900); *Messages of the Masters* (1902), *My Brother* (1910); *Preludes and Interludes* (1911).

BRADFORD, GAMALIEL (1863-). An American writer, born at Boston, Mass. He entered Harvard College in 1882, but was obliged to leave on account of ill health. After 1886 practically all his time was given to writing. He is author of *Types of American Character* (essays, 1895); *The Private Tutor* (1904); *A Pageant of Life*, poems (1905); *Between Two*

Masters (1906); *Matthew Porter* (1908); *Lee, the American* (1912).

BRADFORD, JOHN (c.1510-55). An English minister, born in Manchester. He was secretary to John Harrington of Exton, paymaster of the English forces in France, and was accused of using money not his own because he made restitution of a sum of money which his master had unlawfully taken. In 1547 he began to study law, but turned to the study of divinity and became a fellow of Pembroke Hall, Cambridge, in 1549, and prebendary of St. Paul's, London, in 1551. He was also chaplain to Edward VI and one of the most popular preachers in the kingdom. When Mary came to the throne, he was accused of sedition and tried before Gardiner, and was condemned and burned at the stake at Smithfield, July 1, 1555. Many of his short works are found in the issues of tract societies. There is a complete edition, with a life by Rev. Aubrey Townsend (1848-53).

BRADFORD, WILLIAM (1589-1657). One of the leaders and the historian of the Massachusetts Pilgrims, and the second Governor of Plymouth Colony. He was born in Austerfield, Yorkshire, England; joined the Separatist church of John Robinson (q.v.) at the age of 17, and, after an unsuccessful attempt to leave England in 1607 (for which he was for a time imprisoned), joined the Pilgrims in Holland, where he became a silk dyer and afterward a merchant. He advocated the removal to America and was one of the Pilgrims who in 1620 came over in the *Mayflower* and founded Plymouth Colony. In April, 1621, he was chosen Governor to succeed Carver, and by repeated reflections continued to hold this position until his death, except for five years, when "by importunity he got off." During all this period the story of his life is inseparably connected with that of the Colony, and by his wisdom, his tact, and his great administrative ability, he did perhaps more than any other one man to make the experiment a success. In particular he quickly saw the pernicious effects of the communal system and in 1625 insisted that it be abolished. The second patent of Plymouth was issued (in 1629) to "William Bradford, his heirs, associates, and assigns." Bradford rendered an inestimable service to students of American history by preparing a careful *History of Plymouth Plantation* (from 1602 to 1647), upon which, directly or indirectly, all subsequent accounts of the Pilgrims have been based. This history, says Tyler (*History of American Literature*, vol. i, p. 118), "is an orderly, lucid, and most instructive work; it contains many tokens of its author's appreciation of the nature and requirements of historical writing, and though so recently published in a perfect form, it must henceforward take its true place at the head of American historical literature" and win for its author "the dignity of being called 'the father of American history.'" The manuscript of this work was used by Morton in the preparation of his *New England's Memorial* (1669); by Prince in the preparation of his *Chronological History of New England* (1736), and by Hutchinson in the preparation of his *History of Massachusetts Bay* (1767). It was stored for many years in the tower of the Old South Church, but disappeared during the Revolutionary War; was found in the Fulham Library, England, in 1855; and in 1898 was returned to the United States and deposited among the Massachusetts ar-

chives The history was first published, with notes by Charles Deane, as a volume of the *Collections of the Massachusetts Historical Society* in 1856, and since then has been twice reprinted in facsimile, with an introduction by John A. Doyle (London and Boston, 1896), and under the title, *Bradford's History of Plymouth Plantation from the original Manuscript, with a Report of Proceedings Incident to the Return of the Manuscript to Massachusetts* (Boston, 1898). Of these editions, Deane's is the most useful for the student. His own account of the finding is in *Proceedings of the Massachusetts Historical Society* for April, 1853, vol. III. In addition to the history, Bradford wrote *Some Observations of God's Merciful Dealings with Us in the Wilderness, A Word to Plymouth, A Word to New England, and Epitaphium Meum*—all of which were left in manuscript and have been published in the *Collections of the Massachusetts Historical Society. A Diary of Occurrences Covering the First Year of the Colony*, written in conjunction with Edward Winslow, was published in 1622 and was long known as *Mourt's Relation*, and *A Dialogue, or the Sum of a Conference Between Some Young Men Born in New England and Sundry Advent Men that Came Out of Holland and Old England* was published in 1648, and has been republished in vol. 11 of the *Old South Leaflets* (Boston). Most of Bradford's shorter writings may be found in Young's *Chronicles of the Pilgrims* (Boston, 1841). Consult *The New England Genealogical Register* for 1850, Walker, *Ten New England Leaders* (New York, 1901), Tyler, *A History of American Literature, 1607-1765* (New York, 1898), and Justin Winsor, *Governor Bradford's Manuscript History and its Transmission to Our Times* (Cambridge, 1881). For the circumstances under which the manuscript returned to America, consult G. F. Hoar, "Return of the Manuscript of Bradford's History," in *Proceedings of the Massachusetts Historical Society* (1901-02). For an interesting life of Bradford, consult Cotton Mather, *Magnalia* (London, 1702).

BRADFORD, WILLIAM (1663-1752) An American printer. He was born in Leicester, England, and with other Quakers emigrated to America in 1682. In 1685 he established in Philadelphia the first printing press in the Middle Colonies, and in 1690 he with two others built a paper mill on the Schuylkill. In 1691 he was arrested and tried by the authorities for "seditious libel," his press and publications were confiscated, but the jury refused to convict him. He removed to New York in 1693 and in the same year established the first press in that Colony. On Oct. 16, 1725, he began the first newspaper in New York City, and the fourth in America, *The New York Gazette*. For years he was the only printer in the Colony and for 50 years held the office of public printer. He had two sons, one of whom, Andrew Sowles Bradford (1686-1742), was a prosperous publisher in Philadelphia. Consult Wallace, *An Address at the Celebration by the New York Historical Society of the 200th Birthday of William Bradford* (Albany, 1863).

BRADFORD, WILLIAM (1827-92) An American marine painter. He was born of Quaker parents at New Bedford, Mass., in 1827 or 1830 (the date is variously given), and was educated for business, but developed a talent for painting in middle life. His art was formed

under the influence of Albertus van Beest, whose studio at Farnhaven he shared for two years. With the explorer Dr. Hayes, he undertook several voyages to Nova Scotia and Labrador as far north as Greenland. He is known especially as the painter of icebergs and polar scenery, which he renders with faithful accuracy, but in the hard and dry manner of his day. His paintings were generally exhibited in England, where they enjoyed much popularity. They include "The Steamer Panther among Icebergs and Field-Ice in Melville Bay," exhibited in the Royal Academy (1875) and purchased by Queen Victoria, "Under the Light of the Midnight Sun," "A Squall in the Bay of Fundy," "The Coast of Labrador," "Crushed by Icebergs," "Sunset in the North" (1886), and "Whalers after the Nip in Melville Bay" (1880).

BRADFORD-ON-AVON (AS *Bradford*, from *brād*, broad + *ford*, ford) A market town in Wiltshire, England, on the Avon, and on the Kennet and Avon Canal, 6 miles east-southeast of Bath, and 20 miles northwest of Salisbury (Map, England, D 5). The Avon, which is crossed by two bridges, divides the town into the old and new. The small church of St. Lawrence is one of the few examples of Saxon architecture in England. It was founded by St. Aldhelm in the early eighth century. The present building is now supposed to be a restoration dating from the last quarter of the tenth century and due to Dunstan, Archbishop of Canterbury. The town was noted for many centuries for its manufacture of fine broadcloths. It now manufactures rubber goods and has breweries, quarries, and iron foundries. Pop., 1891, 4943, 1901, 4514, 1911, 4501.

BRADLAUGH, brād'la, CHARLES (1833-01) An English Radical politician and social reformer. He was born in London, Sept. 26, 1833. His early education was meagre, for he had to support himself, at times by running errands. At the age of 17 he enlisted in the army. He secured his discharge in 1853, became clerk to a London solicitor, and soon was noted as an agitator, free-thought lecturer, and as a pamphleteer under the name of "Iconoclast." He published the *National Reformer*. In 1873 he made a short visit to the United States, lecturing in the larger cities. In 1876, with Miss Annie Besant he was sentenced to six months' imprisonment and £200 fine for republishing the Malthusian *Fruits of Philosophy*, but the conviction was quashed on appeal. Elected member of Parliament for Northampton in 1880, he pleaded that as an atheist he had the right to affirm, but when this request was denied, expressed his willingness to take the oath. This the House decided he was disqualified from doing, he was ordered to leave, and on his refusal was placed in custody. His seat was declared vacant by the court to which the case was carried. But his constituency returned him in 1881, he presented himself, was again denied the privilege of taking the oath, and on his refusal to leave the House was forcibly ejected. Similar scenes occurred at the proroguing of Parliament in 1882 and 1883, and in the latter year Bradlaugh won a suit which he brought against the sergeant at arms for unlawful ejection. The case, however, was decided on technical grounds, and the invalidity of his title to a seat in the House was reaffirmed. In 1885 he was again returned for Northampton, and was permitted to take the oath, and shortly before

his death, Jan. 30, 1891, Parliament expunged from its records the resolution forbidding him to take the oaths. Of his writings, *The Impeachment of the House of Brunswick* (Boston, 1875) attained the greatest popularity. It advocated the repeal of the Hanoverian settlement of the crown at the Queen's death. Consult: Headingley, *Biography of Charles Bradlaugh* (London, 1883); Bonner, *Charles Bradlaugh* (London, 1894); Birrell, *In the Name of the Bodleian* (New York, 1905).

BRADLEY, EDWARD (*Cuthbert Bede*) (1827-89). An English author. He was born at Kidderminster, graduated in 1848 at Durham University; was consecrated a priest of the Established church, and was rector of Denton, Strutton (1871-88), and Lenton. He contributed to periodicals and wrote numerous volumes both of prose and verse, of which the best known is *The Adventures of Verdant Green* (1853-57), a humorous story of life at Oxford.

BRADLEY, GEORGE GRANVILLE (1821-1903). An English clergyman. He was educated at Rugby and Oxford, served as assistant master at Rugby, became head master of Marlborough College in 1868, and was ordained in the same year. In 1870 he was made master at University College, Oxford. He was honorary chaplain to the Queen from 1874 to 1876 and succeeded A. P. Stanley as dean of Westminster in 1881. Among his publications are *Recollections of Arthur Penrhyn Stanley* (1892); *Lectures on Job* (1884); *Lectures on Ecclesiastes* (1885); *Life of Dean Stanley* (1892); *Aids to Writing Latin Prose Composition* (1892).

BRADLEY, HENRY (1845-). An English scholar. He was born in Manchester, Dec. 3, 1845; was educated at Chesterfield Grammar School; spent some time in teaching and was employed as clerk and foreign correspondent at Sheffield till 1884, when he went to London. Bradley has contributed to periodicals and encyclopedias and edited or revised several philological works. In 1889 he became one of the editors of the great Oxford English Dictionary. Two notable works of his are: *The Story of the Goths* (1888); and *The Making of English* (1904).

BRADLEY, JAMES (1693-1762). An English astronomer. He was born at Sherborne in Gloucestershire and was educated at Oxford. Afterward he studied with his uncle, the Rev. James Pound, who was at that time one of the best astronomers in England. He was elected a fellow of the Royal Society in 1710. In 1721 he was appointed to the Savilian chair of astronomy at Oxford University. In 1729, after repeated observations, he announced his important discovery of the aberration of light. The theory advanced by Bradley to explain this complex phenomenon has remained practically unchanged. (See *ABERRATION OF LIGHT*.) In 1742 Bradley, who had been styled by Newton "the best astronomer in Europe," was appointed Astronomer Royal and entered upon a career of great activity at Greenwich. Several years afterward he discovered nutation, or the inconstancy of the inclination of the earth's axis to the ecliptic. For this discovery he received the Copley medal in 1748. In the same year he secured a new instrumental outfit for the Royal Observatory, by means of which the foundations of modern sidereal astronomy were laid. He left at his death 13 manuscript volumes of observations, which were published in 1798-1805.

The value of these observations was enormously increased by Bessel, who undertook their systematic reduction and extracted from them the catalogue of 3222 stars which he published in 1818 under the appropriate title of *Fundamenta Astronomiae*. Bradley's observations of the moon and the planets were reduced by Airy and afforded valuable data for the correction of the lunar and planetary theories. His *Miscellaneous Works and Correspondence* was published in 1832.

BRADLEY, JOSEPH PHILLO (1813-92). A distinguished American jurist, born at Berne, N. Y. He graduated at Rutgers in 1836, was admitted to the New Jersey bar in 1839, was retained as counsel to various railway corporations, and became prominent in several cases of importance. In 1870 he was appointed an associate justice of the United States Supreme Court and assigned to the Fifth Circuit (Gulf States, Georgia to Texas), from which he was subsequently transferred to the Third (Pennsylvania, New Jersey, and Delaware). He was a member of the Electoral Commission of 1877, which decided the election of 1876 in favor of Hayes, and supplemented his vote by an opinion noteworthy for logical clearness. A profound and discriminating student of the law, he was in particular distinguished for opinions on civil rights, the right of habeas corpus and admiralty jurisdiction, and in those involving constructions of the Federal Constitution. In 1870 he pronounced the centennial address at Rutgers College. His *Miscellaneous Writings* were published in 1902 with a biographical introduction.

BRADLEY, MISS K. H. See **FIELD, MICHAEL**.
BRADLEY, WILLIAM O'CONNELL (1847-1914). An American public official and legislator, born near Lancaster, Garrard Co., Ky. He was admitted to the bar in 1865, was elected prosecuting attorney of Garrard County in 1870, and was presidential elector in 1872. In the Republican National Convention of 1880 he made a speech seconding the nomination of Grant for President, in 1884 he defeated the movement to curtail southern representation in the Republican National Convention, four years later he received 105 votes for the vice-presidential nomination, and in 1904 he seconded the nomination of Roosevelt for President. For twelve years he was a member of the Republican National Committee. In 1895-99 he was Governor of Kentucky. He became United States Senator for the term of 1909-15.

BRADSHAW, HENRY (c.1450-1513). An English writer of verse and Benedictine monk of Chester. He wrote a Latin treatise, *De Antiquitate et Magnificentia Urbis Cestrie* (1513); and a *Life of St. Werburgh* (1500), in English verse. *The Holy Lyfe and History of Saynt Werburge* was published posthumously (1521).

BRADSHAW, JOHN (1602-59). An English Commonwealth judge, famous as one of the regicides. He was born near Stockport, Cheshire. He studied law and was called to the bar at Gray's Inn, 1627. He gained a good practice by his ability and learning, held several offices, and was elected president of the High Court of Justice for the trial of King Charles I in 1649. As the reward of his services at that occasion, he was made President of the Council of State, and Chancellor of the Duchy of Lancaster; he also received a grant of estates worth £2000 per annum. Bradshaw, however, frequently opposed the Protector when unable to see or comprehend

the necessity for his rigid rule. After Cromwell's death and the abdication of Richard Cromwell, he was Lord President of the Council of State, and a commissioner of the Great Seal. He was a friend of Milton, who eulogized him. He died in London, Oct. 31, 1659. His body was buried with pomp in Westminster Abbey, but at the Restoration was exhumed and hung on a gibbet, with those of Cromwell and Ireton.

BRADSTON. See BRAXY.

BRADSTREET, ANNE (c 1612-72). An American poet. She was born at Northampton, England, about 1612. Mrs. Bradstreet was a daughter of Gov. Thomas Dudley. She married the future Governor Bradstreet in 1623, went with him to New England (1630), and in the intervals of household duties involved in the rearing of eight children became a voluminous author, who won for herself from her compatriots the admiring designation, "The Tenth Muse." Her poems were published under a title which gives a tabular view of their contents, to wit: *Several Poems Compiled with Great Variety of Wit and Learning, Full of Delight, Wherein Especially is Contained a Complete Discourse and Description of the Four Elements, Constitution, Ages of Men, Seasons of the Year, Together with an Exact Epitome of the Three First Monarchies, viz., The Assyrian, Persian, and Grecian, and the Beginning of the Roman Commonwealth, to the End of Their Last King, with Divers Other Pleasant and Serious Poems by a Gentlewoman of New England* (London, 1650). It is on the title-page of this edition that she is called "The Tenth Muse." The *Four Monarchies* (1867) is based on Sir Walter Raleigh's *History of the World*, but she drew her chief poetic inspiration from Sylvester's translation of *The Creation*, by Dr. Bartas (q.v.), 1606. A second edition appeared at Boston in 1678, with additions, among which is *Contemplations*, her best poem. Her complete *Works*, which include certain memorials of her life and prose aphorisms, were edited by J. H. Ellis (1867), and for the Society of the Duodecimos (1897), with an introduction by Charles Eliot Norton. Mrs. Bradstreet's verses are in the main lacking in poetic power, and the modern reader wonders at the admiration they excited. Cotton Mather said they "would outlast the stateliest marble." Her contemporaries "weltered in delight" or were "sunk in a sea of bliss" at their perusal. They were at least the best of her generation in America. They show an indomitable assertion of a woman's right to thought and learning. She deserves an honored place in the history of New England culture, as one of the first writers in America devoted to literature for its own sake. Consult Wendell, *A Literary History of America*, pp. 36, 40, 119 (New York, 1900).

BRADSTREET, JOHN (1711-74). An English soldier, who spent nearly his whole life in service in North America. In 1745 he served in the Louisiana expedition as lieutenant colonel in Popperell's regiment and later in the year was raised to the rank of captain. In 1746 he was appointed Lieutenant Governor of St. John's, and in 1755 became adjutant general under General Shirley (q.v.). During the summer of 1756 he was in charge of the conveying of a large quantity of stores from Albany to Oswego and was attacked by a strong party of French, whom he defeated. He took part in the attack on Ticonderoga in 1758 and immediately

thereafter became quartermaster, with the rank of colonel. On August 27 of this year he captured Fort Frontenac and in 1759 accompanied General Amherst on his expedition against Ticonderoga and Crown Point. He commanded an expedition against the Indians during the Conspiracy of Pontiac and on Sept. 7, 1764, made a treaty with them at Detroit. In 1772 he became a major general.

BRADSTREET, SIMON (1603-87). An early Colonial Governor of Massachusetts, born in Horbling, Lincolnshire, England. He was educated at Cambridge and in 1630 emigrated to America and settled at Cambridge, Mass. He was an assistant judge, and was successively secretary, agent, and commissioner of the United Colonies. In 1662 he was sent to congratulate Charles II on his restoration. He was Assistant from 1630 to 1679, was Deputy Governor from 1673 to 1679, and was Governor from 1679 to 1686, when the Massachusetts charter was revoked. He was restored to office in 1689 and remained in power until the new charter arrived in 1692, when he was made first counselor. He was generally popular as a magistrate, though in several instances, notably with regard to the witchcraft delusion of 1692, he was opposed to the majority of the colonists. His wife was Anne Bradstreet, the poet, daughter of Thomas Dudley (q.v.).

BRADWARDINE, BRAD'WARDEN, THOMAS (c 1290-1343). An English scholar, born at Hatfield in Sussex. He early acquired the reputation of being a profound scholar, skillful mathematician, and able divine, which won him the title "Profound Doctor." He was chancellor of the university, later became confessor to Edward III, and finally was consecrated Archbishop of Canterbury, but died of plague shortly after his consecration. Part of Bradwardine's mathematical work was on star polygons, a subject which fascinated the great Kepler, Regiomontanus, and Cardan, and which has attracted much attention in recent times. The trigonometry of the Arabs was known to him, and his philosophic works contain discussions of the infinite and the infinitesimal. His chief works are *De Causa Dei* (1618), *De Geometria Speculativa* (1495, 1512, 1530), *De Proportionibus* (1495), *De Quadratura Circuli* (1495), *De Arithmetica Practica* (1502). Consult Hahn, *Thomas Bradwardinus* (Munster, 1905).

BRADY. A city and the county seat of McCulloch Co., Tex., 108 miles (direct) northwest of Austin, on the Frisco Lines and the Gulf, Colorado, and Santa Fe railroads (Map Texas, C 4). Brady is in a rich agricultural region, raising extensively cotton, pecans, wool, mohair, cattle, and stock. It has cotton oil and planing mills, gins, a compress, a creamery, and an ice plant. The city, incorporated in 1906, is governed by a mayor and board of aldermen, and owns its water works and electric light plant. Pop., 1900, about 700, 1910, 2669.

BRADY, AGÉNOR. See BARDOUX, AGÉNOR.

BRADY, ANTHONY NICHOLAS (1843-1913). An American capitalist, born at Lille, France. His parents came to the United States when he was a child, and he attended school in Troy, N. Y. After being employed in various ways for some years, he opened a tea store in Albany, and by gradually forming a chain of stores dealing in tea gained virtual control of the local sale of this commodity. Subsequently he became interested in granite quarries and in nu-

merous public utilities and staple products. He was one of the organizers of the Metropolitan Traction Company in New York City and, participating in 1887 in the reorganization of the Brooklyn Rapid Transit Company, was at the time of his death chief of its board of directors. He had large holdings also in Washington and Philadelphia street railways, in the New York Edison Company, and in powerful tobacco, rubber, and iron-pipe corporations.

BRADY, CYRUS TOWNSEND (1861-). An American clergyman and author, born in Allegheny, Pa. He graduated in 1883 at the United States Naval Academy, and after work in connection with Western railways was in 1890 ordained priest of the Protestant Episcopal church. He was rector of churches in Missouri and Colorado and subsequently was appointed Archdeacon of Kansas. From 1895 to 1899 he was Archdeacon of Pennsylvania, and thereafter he had charges at Philadelphia (1899-1902), Toledo (1905-06), Kansas City (1909-13), and Mt. Vernon, N. Y. (1913-14). During the Spanish-American War he was chaplain of the First Pennsylvania Volunteers. He published lives of *Stephen Decatur* (1900) and *Commodore Paul Jones* (1900); *Recollections of a Missionary in the Great West* (1900), his best work; *Border Fights and Fighters* (1902); *Sir Henry Morgan, Buccaneer* (1903); *Indian Fights and Fighters* (2 vols., 1903-07); *The Conquest of the South West* (1905), and much fiction, including *The Love Test* (1908), *The Ring and the Man* (1909); *The Better Man* (1910); *As the Sparks Fly Upwards* (1911); *The Master of Reparaté* (1912); *The Fetters of Freedom* (1913).

BRADY, FRANCIS XAVIER (1857-1911). An American Catholic priest and educator, born near Gettysburg, Pa. He entered the Society of Jesus; studied at Woodstock College, Md., in 1876-79 and (after teaching at Gonzaga College, Washington, D. C., in 1884-86) was ordained a priest in 1886; and until 1892 was director of the Sacred Heart League of the United States and edited Catholic periodicals. He was vice president of Loyola College, Baltimore, in 1892-95, and its president after 1908, having had charge of St. Ignatius's Church, Baltimore, in the interval. He wrote a biography of St. Aloysius (1887) and devotional works, including *The Holy Hour* (1890) and *The Great Supper of God* (1901).

BRADY, GEORGE STEWARDSON (1832-). An English zoologist and paleontologist. He was born at Gateshead-on-Tyne and was educated at the University of Durham. He practiced medicine and surgery in Sunderland after 1857 and became professor of natural history in the Durham College of Science and consulting physician to the Sunderland Infirmary. His principal published works are: "A Monograph of the Recent British Ostracoda," in *Transactions of the Linnean Society* (1863); *A Monograph of the Post-Tertiary Entomostraca of Scotland* (1874); *A Monograph of the Free and Semi-Parasitic Copepoda of the British Islands* (1877-80).

BRADY, HENRY BOWMAN (1835-91). An English paleontologist, born at Gateshead. He was a successful manufacturing pharmacist and had much influence in placing that profession on a sound scientific basis. For several years he was member of the council of the Pharmaceutical Society. The associations of his youth had

developed in him a desire for research in natural history, and his life near the coast of the North Sea enabled him to gratify his tastes in that direction. He spent much time in dredging marine animals and became particularly interested in a group of minute organisms, the Foraminifera, concerning which he eventually was recognized as the chief English authority. He studied also the fossil members of this group of animals. The oceanic deposits collected by the *Challenger* expedition were turned over to him for examination, and the contained Foraminifera furnished the material for an extensive monograph, perhaps the most important ever published on that class of animals. He published several memoirs on the Foraminifera of the Mesozoic, Cenozoic, and recent deposits of Great Britain, and contributed freely to the scientific journals. He was elected a fellow of the Geological Society of London in 1884, of the Royal Society in 1874, and was also a fellow of the Linnean and the Zoological societies. His more important works are: *Report on the Foraminifera Dredged by H. M. S. Challenger, during the Years 1873-76* (2 vols., 1884); *Scientific Results of the Challenger Voyage*, vol. ix (1888), a magnificent work of over 800 quarto pages, with an atlas of 115 plates, "A Monograph of Carboniferous and Permian Foraminifera," *Transactions Paleontographical Society*, vol. xxx (1876).

BRADY, JAMES HENRY (1862-). An American public official and legislator, born in Indiana Co., Pa. He studied at the State Normal School at Leavenworth, Kans. In 1894 he moved to Idaho where he became president of the Idaho Consolidated Power Co. He also became president of the Western Development Association, and chairman of the advisory board of the National Council of Women Voters. In 1904-08 he was chairman of the Idaho Republican State Central Committee, and in 1909-11 was Governor of Idaho. He was elected United States Senator in 1913 to fill the vacancy caused by the death of Senator Heyburn.

BRADY, JAMES TOPHAM (1815-69). An American lawyer, born in New York City. He was educated by his father, who was also a well-known lawyer and judge. The son became eminent for his forensic eloquence and met with remarkable success as a lawyer, especially in criminal cases. In 1843 he was appointed district attorney of New York County and in 1845 corporation counsel of the city of New York. In 1860 he was the candidate of the proslavery Democrats for Governor of New York State. He contributed largely to newspapers and magazines, but left no collected works. Among his notable criminal cases was the defense of Gen. Daniel E. Sickles, on trial for killing Philip Barton Key.

BRADY, JOHN (1842-1910). An Irish-American prelate, born in county Cavan, Ireland. He studied at All Hallows College, was ordained priest in 1864, and from 1864 to 1868 was assistant pastor at Newburyport, Mass. In 1868 he became pastor at Amesbury, Mass. He greatly aided Archbishop Williams, of Boston, in the labors of that episcopate and was appointed auxiliary Bishop of Boston in 1891. In the same year he was consecrated titular Bishop of Alabama.

BRAEKELEER, brä'ke-lär, DE. A family of Belgian painters.—FERDINAND TIEBLEN (1792-1883), historical and genre painter, was

born in Antwerp and studied at the Academy there under Van Bree. His most important activity was as a teacher. Besides his sons and nephew, he numbered among his pupils such important artists as Leys, Alois Hunn, and Louis Somers. He began with large historical canvases, which he abandoned in favor of genre pictures, showing in their color the influence of the old Flemish masters.—HENRI DE BRAEKELEER (1800-88), born in Antwerp, was a pupil of his father and his uncle Leys (qv). He sought for inspiration in the old Dutch masters, especially Pieter de Hoogh, and emphasized rather the technical side than the subject of his paintings.—FREDYAND THE YOUNGER (1828-57), likewise a pupil of his father and of Leys, painted genre interiors of great promise, which an early death prevented him from fulfilling. The works of the Braekelers may be best studied in the museums of Brussels and Antwerp. Henri is also represented in Berlin and Hamburg. Consult Hymans, *Henri de Braekeler* in *Kunst und Künstler* (Berlin, 1905), C. Lemouner, *Henri de Braekeler et son œuvre* (Brussels, 1905).

BRAG (from *brag*, to boast, of the game of bluff). An old English game at cards, of which there are two varieties, single and three-stake *Brag*. The full pack of cards is used. The three bragger cards, in order of their value, are the ace of diamonds, the jack of clubs, and the nine of diamonds. All of the other cards rank as in draw poker. The braggers may be used as duplicates of any other card, but a natural pair, etc., ranks higher than one made with a bragger. The rules governing the game are those which control poker. Pairs and triplets only count. In *Three Stake Brag* each player puts up three equal (and invariable) amounts. The dealer deals to each player two cards, faces down, and then one card, face up. The highest turned-up card wins the first pool. The play then continues with the other two cards, the winner taking the second pool, when all the remaining hands are shown, the winning one being that whose spot value is nearer to 31, reckoning the aces at 11 and the face cards at 10 each. In *American Brag*, there are eight braggers, all of equal value, the jacks and nines of each suit, but a pair or triplets formed with a bragger outrank a natural. If a player raises a bet, and another player sees the raise, the two change hands, and the holder of the lower hand retires, returning the higher hand to the original holder. Consult Foster's *Complete Hoyle* (New York, 1909).

BRAGA, bra'ga (Lat. *Bracara*, so called from the tribe *Bracarii*). The capital of a district in the Portuguese province of Minho and seat of an archbishop, 33 miles west-northwest of Oporto (Map Portugal, A 2). It is an old town, antedating its colonization by the Romans. Surrounded by walls and towers and containing a number of old buildings, it still stands practically in its medieval form, in the midst of its modern suburbs. There are Roman ruins of a temple, an amphitheatre, and an aqueduct. The cathedral, originally built in the twelfth century and altered since then, contains a number of relics relating to the early history of Portugal, but is of little architectural value. There is also an archiepiscopal palace, with a fine library, and a number of smaller churches and monasteries. In the vicinity is situated the church of Bom Jesus do Monte, visited annually

at Whitsuntide by thousands of pilgrims. Braga is of some industrial importance, producing hats, arms, textiles, and gold and silver articles. Pop., 1890, 23,080, 1900, 24,300. Braga was the capital of Lusitania and the seat of two councils held in the sixth century at which the Arian and the Priscillianist heresies were respectively renounced. These councils mark the origin of the ecclesiastical greatness of Braga, whose archbishop is the Primate of Portugal, and long claimed supremacy (never acknowledged by the Cardinal Archbishop of Toledo) even over the Spanish church.

BRAGA, THEOPHILUS (1843-) A Portuguese philologist, poet, literary historian, philosopher, and statesman, born on the island of San Miguel, Azores. He studied law at the University of Coimbra and in 1872 was appointed professor of modern languages in the *Curso Superior de Letras* of Lisbon. He is the most important of modern Portuguese writers, known in his own country through his presentation of the positivism of Comte, his great history of Portuguese literature, and his militant democracy in politics. In his *Povo português no seus costumes, crenças e tradições* (2 vols., Coimbra, 1885), he presents a profound study of the Portuguese people and their relation to the Spanish people. Beyond Portugal he is best known for his investigation regarding the philology and literature of the Spanish Peninsula. His work in that field has been far too extensive wholly to escape a certain lack of exactness, yet his contributions to a critical knowledge of the subject have been noteworthy. From 1880 to 1886 he edited the periodical *O Positivismo*. After the overthrow of the monarchy he was provisional President of Portugal from Oct. 4, 1910, to the end of August, 1911. A much-abridged list of his works includes *História da poesia popular portuguesa* (1867, new ed., 1902), *História da literatura portuguesa* (32 vols., 1870-81, new ed., 10 vols., 1902, and a still later edition in some 30 volumes in course of publication in 1913), *Theoria da história da literatura portuguesa* (1872), *Manual da história da literatura portuguesa* (1875), *Traços geraes de philosophia positiva* (1877), *Soluções positivas da politica portuguesa* (1879), an excellent life of Camoens (1880), and a selection of poems, entitled *Alma Portuguesa* (1893), *Garrett e a sua obra* (1905). Consult T. Bastos, *Theophilo Braga e a sua obra* (Porto, 1893).

BRAGANÇA, bra-gan'sa. The name of two considerable towns in Brazil. 1. A seaport in the state of Pará, at the mouth of the Cato, which enters the Atlantic about 100 miles to the east of the Rio Pará estuary (Map Brazil, H 4). It is 110 miles northeast of Pará, with which it is connected by a railroad. Pop., 6000. 2. An inland city of about 17,000 inhabitants, in the state of São Paulo, 70 miles north of Santos, with which it is connected by rail, and about 200 miles to the west of Rio de Janeiro (Map Brazil, H 8).

BRAGANÇA. A city of Portugal, capital of a district in the province of Traz-os-Montes, situated in a pleasant and fertile district, on the Fervença, an affluent of the Sabor (Map Portugal, B 2). It is surrounded with walls and was the ancestral seat of the Dukes of Bragança (Braganza). There are some manufactures of silk and velvet. Pop., 1890, 5840, 1900, 5476. See BRAGANZA, HOUSE OF.

BRAGANZA, brăg'in'ză, HOUSE OF. A reigning house of Portugal, originally Dukes of Braganza (see BRAGANCA), represented through the female line in the exiled King Manoel. The first Duke was Alfonso de Portugal, a bastard son of King John I and Ines Pires. He was created Duke of Braganza in 1442 by his brother, Pedro de Portugal, acting as regent during the minority of Alfonso V. The sixth Duke, John, married Catherine, elder daughter of Edward, Duke of Guimaraens, a younger brother of John III. Catherine had better rights to the throne of Portugal than those alleged by Philip II, when in 1580 he took possession of Portugal. Sixty years later (1640) her lineal descendant, the eighth Duke John of Braganza, became King John IV of Portugal. Although the house of Braganza died out in the male line (after having founded the Imperial line of Brazil, which has also died out in the male line), its lineal descendants through the female line (house of Saxe-Coburg-Gotha-Braganza) continued to occupy the throne of Portugal until the expulsion of King Manoel II in 1910.

BRAGELONNE, brăzh'lün', LE VICOMTE DE, ou DIX ANS APRÈS. The title of a novel by the elder Dumas (1848), the last of the trilogy of which *Les trois mousquetaires* was the first.

BRAGG, BRAXTON (1817-76). An eminent Confederate general in the American Civil War. He was born in Warren Co., N. C.; graduated at West Point in 1837, and served in the Seminole War in 1837-39, and again in 1841-42. During the Mexican War he served under General Taylor, and for "gallant and distinguished conduct" at Fort Brown, Monterey, and Buena Vista was brevetted captain, major, and lieutenant colonel, respectively. He was on duty in various garrisons until January, 1859, when he left the service to become a sugar planter in Louisiana. From 1859 to 1861 he was commissioner of the Louisiana Board of Public Works. He joined the Confederate army on the outbreak of the Civil War, was made brigadier general early in 1861, and soon afterward was placed in command at Pensacola, Fla., of the Confederate forces which operated against Fort Pickens. He was promoted to be major general in February, 1862; joined the Army of Mississippi; took a conspicuous part in the battle of Shiloh (April 6-7); and, after the death of A. S. Johnston, was raised to the rank of general. On June 20, 1862, after the evacuation of Corinth, he replaced General Beauregard as commander of the Western Department, and in August, at the head of a force of 45,000, invaded Kentucky, with the intention of winning over that State to the Confederate cause. An exciting race for Louisville ensued between him and Buell, but Buell arrived first and by skillful maneuvering gradually forced him to retreat. The two armies met at Perryville, Ky., on October 8, and Bragg, defeated, withdrew hastily into Tennessee.

His apparent failure in this campaign brought upon him the bitter criticism of the South, and for a time his removal was seriously contemplated; but his campaign, according to Gen. T. A. Dodge, "had really placed him in a position in Buell's front far superior to the one he had occupied before he marched for the Ohio, morally and materially." At Murfreesboro, or Stone River, on Dec. 31, 1862, and Jan. 2, 1863, he was again worsted by the Federal army, now under Rosecrans, and fell

back upon Tullahoma. Out of this city, early in September, 1863, he was skillfully maneuvered by Rosecrans, whom, however, he defeated decisively in the great battle of Chickamauga (September 19-20). Soon afterward he was utterly defeated, in turn, by Grant in the three days' battle of Chattanooga (November 23-25), and, in deference to the growing dissatisfaction of his army, he was replaced by Hardee on December 2. On Feb. 24, 1864, he was summoned to Richmond, where, under the direction of President Davis, he was charged with "the conduct of military operations in the armies of the Confederacy." He was placed in command of the Department of North Carolina in November, and led an unsuccessful expedition into Georgia to cooperate against Sherman, then on his march to the sea. In February, 1865, he was assigned to active service under J. E. Johnston and remained with that officer until his surrender. After the war Bragg was for some time chief engineer for the State of Alabama and as such had charge of the improvements in Mobile Bay. He was a hard fighter, and as an officer was brave and resourceful; but he was also a stern martinet, was sometimes dilatory in his movements, and was frequently lax in supervising the execution of his orders.

BRAGG, EDWARD STUYVESANT (1827-1912). An American politician born at Unadilla, N. Y. He settled in Wisconsin, and was admitted to the bar of that State in 1850. From 1854 to 1856 he was district attorney for Fond du Lac Co., Wis. He entered the army as a captain in 1861 and was mustered out as a brigadier general in 1865. He was in Congress in 1877-83 and 1885-87, and in 1884 seconded the nomination of Cleveland, saying of him, "We love him for the enemies he has made." He was Consul General to the Cuban Republic from May to September, 1902, and held the same position at Hongkong from 1902 to 1906.

BRAGGADOCCHIO, brăg'gă-dŏ'chŏ (evidently from bragging). A character in Spenser's *Faerie Queene*, representing the twin vices of boasting and cowardice, and drawn from Ariosto's *Martano in Orlando Furioso*.

BRAGI, bră'gē, or BRAGE. In Scandinavian mythology, the god of poetry and eloquence, son of Odin and Frigga. According to the Older Edda he was the most perfect of all skalds, or poets, and the inventor of poetry, which is designated by a kindred word, *bragr*. One of the books of the Younger Edda is called *Bragi's Talk*. Unlike Apollo, who in the Greek mythology is represented as enjoying eternal youth, Bragi was supposed to be an old man with a long, flowing beard, and his brow was always mild and unwrinkled. Bragi's wife was Idun (q.v.). Together with Hermod he received and welcomed all those heroes who had fallen in battle on their arrival at Walhalla. On festive occasions, as well as at the burial of a king or earl, a goblet, called Bragafull (Bragi's goblet), was presented, before which each man arose, made a solemn vow to do some great deed worthy of being immortalized in verse, and emptied it. The Danish King Sweyn is said to have made such a vow before the invasion of England in 994. The myth of Bragi was probably developed from the earliest-known Norse skald of the same name, who lived c.800, and of whose fragmentary works there is an edition by Gering (Halle, 1886). Several German periodicals and other works intended to cherish a national spirit

have taken the name of Bragi. Consult Anderson, *Norse Mythology* (Chicago, 1901). See **ESB**.

BRAHAM, brá'am, JOHN (1774-1856) A well-known English singer, of Jewish descent, born in London. He had an unusually long professional career, having begun to sing on the stage at the age of 10. About the close of the eighteenth century he visited France and Italy for study. On his return to England he became remarkably popular, and from that time for half a century he was considered the greatest tenor in Europe. Sir Walter Scott considered him "a beast of an actor, but an angel of a singer." He created the rôle of *Huon* in Weber's *Oberon*. He also wrote incidental music to many plays.

BRAHE, bra or bra'a, TYCHO (1546-1601) A celebrated Danish astronomer, born at Knudstrup in Skåne, south Sweden, then a province of Denmark. He was descended from a noble family, originally Swedish, and was sent at the age of 13 to the University of Copenhagen, where he had not been more than a year when an eclipse of the sun turned his attention to astronomy. His uncle, who destined him for the law, furnished him with a tutor, and sent him to the University of Leipzig in 1562, but Brahe, who cared nothing for that study, devoted just so much time to it as would save appearances, and while his tutor slept busied himself nightly with the stars. By these surreptitious observations of the heavens, and with no other mechanical contrivances than a globe about the size of an orange and a pair of rude compasses, he succeeded, as early as 1563, in detecting grave errors in the Alfonsine and Prutenic tables and set about correcting them. The death of his uncle, who left him an estate, recalled him to his native place in 1565, but he very soon became disgusted with the ignorance and arrogance of those moving in the same sphere with himself and went back to Germany. He resided at Wittenberg for a short time, and then went to Rostock, where he lost part of his nose in a duel with a Danish gentleman, but for the lost organ he ingeniously contrived one of gold, that fitted so admirably, and was so naturally colored, that few could have detected that it was artificial. After a couple of years spent in Lüneburg he returned home, where in 1572 he discovered a new and brilliant star in the constellation Cassiopeia. In 1573 he married a peasant girl, which his fellow noblemen thought even more undignified than being addicted to astronomy, for thus they considered very degrading to a gentleman, whose only becoming qualification should be, in their estimation, skill in the use of arms. After some time spent in travel, Brahe received from his sovereign, Frederick II, the offer of the island of Hven as the site for an observatory, the King also offering to defray the cost of erection and of the necessary astronomical instruments, as well as to provide him with a suitable salary. Brahe accepted the generous proposal, and in 1576 the foundation stone of the castle of Uraniborg ('fortress of the heavens') was laid. Here, for a period of 20 years, Brahe prosecuted his observations with the most unwearied industry—with a zeal, in fact, sufficient to create a new epoch in astronomy as a science of observation. The scientific greatness of Brahe was no protection against the petty prejudices of the nobles, who could not bear to see honor heaped

on one who, according to their notions, had disgraced their order, nor against the meaner jealousies of physicians, who were annoyed at his dispensing medicine gratis to the poor. So long as his munificent patron, Frederick II, lived, Brahe's position was all that he could have desired, but on his death, in 1588, it was greatly changed. For some years under Christian IV, Brahe was simply tolerated, but in 1597 his position had grown so unbearable that he left the country altogether, having been the year before deprived of his observatory and emoluments. After residing a short time at Rostock and at Wandsbeck, near Hamburg, he accepted an invitation of the Emperor Rudolph II—who conferred on him a pension of 3000 ducats—to Benátky, a few miles from Prague, where a new Uraniborg was to have been erected for him, but he died at Prague on Oct. 24, 1601 (N.S.). At Benátky he had Kepler as his assistant, and to the advice of Brahe that celebrated astronomer owed much.

Brahe never fully accepted the Copernican system of the universe, and sought to compromise by combining it with the old Ptolemaic system. In the Tychoenic system the planets were considered to move round the sun, which, together with the stars, revolved about the earth, the latter remaining fixed in space. Brahe rediscovered the variation and annual equation of the moon first detected by the Arabian astronomer, Abul Wefā, and computed the earliest refraction tables. He may be said to have inaugurated the era of precision in astronomical measurement. Had it not been for the exactness of his observations, Kepler might have sought in vain for the three laws of planetary motion which are associated with his name.

The scientific publications of Brahe are numerous. His principal work, *Astronomiæ instauratæ Progymnasmata*, in 2 vols., ed. by Kepler, appeared at Prague in 1602-03. In his *Astronomiæ instauratæ Mechanica*, published at Wandsbeck in 1598, he gave a description of his instruments and an autobiographical account of his life and discoveries. Complete editions of his works were printed at Prague in 1611 and at Frankfurt in 1648. Consult Gassendi, *Vita T. Brahe* (Paris, 1655); Biewster, *Martyrs of Science* (London, 1841); Bertrand, *Les Fondateurs de l'astronomie moderne* (Paris, 1873); Dreyer, *Proetus of Scientific Life and Work of Tycho Brahe* (London, 1890); Lodge, *Pioneers of Science* (London, 1904); Bryant, *History of Astronomy* (London, 1907); Bigourdan, *L'astronomie, Evolution des Idées et des Méthodes* (Paris, 1911); *Tychonis Brahe Dani Opera Omnia*, Tom I, edited by Dreyer (Copenhagen, 1914).

BRAHMA, bra'ma. According to its commonest usage, the name of the Supreme Being, or Creator of the Universe, in the Hindu religion and philosophy. The Sanskrit word *brahman* itself has three distinct phases, which are important to note: (1) *brāhmaṇ*, neuter and accented on the first syllable, with nominative singular *brāhmā*, signifies exaltation, force, especially the power of prayer, devotion, worship, and later, holiness, spirit, the all-pervading essence of the universe, (2) *brahmān*, masculine and accented on the ultima, with nominative singular *brahmā*, denotes a personification of the latter, the Supreme Creator of the Universe, (3) *brahmān*, also masculine and similarly accented, denotes a priest, a Brahman. The first

two meanings alone are considered here; for the third see BRAHMANISM; CASTE.

In the *Rigveda* *brāhmā*, neuter, signifies only the power of prayer; in the later development of the Brahmanas and Upanishads (q.v.) it denotes the essence of the universe from which all created things are evolved and into which they are reabsorbed. The personified god *Brahmā*, masculine, is a deified form of this absolute spirit, and to know him is the step toward the higher knowledge of the impersonal and supreme soul. *Brahma* as a divine being represents creative activity, and he shares respectively with the other two members of the Hindu Trinity, *Vishnu* and *Śiva*, in producing, maintaining, and dissolving the world. As a formal triad this union is of later origin in the development of Hindu mythology. The attribute of creative activity is ascribed to various gods in the older Vedic period; but in the stage of the Brahmanas, the father god, *Prajāpati*, or *Brahmā*, appears as the individual creator. In *Manu* (q.v.), i. 1 et seq., *Brahmā* is described as self-existent and as evolving the world from an egg—the doctrine of the cosmic egg—and his existence endures for an æon that is practically eternal. The representations of *Brahmā* in Hindu mythology often show him as born in a lotus sprung from the navel of *Vishnu*. Five heads were originally assigned to him, but one was destroyed by *Śiva*. His color is red, and he rides upon a swan. The goddess *Sarasvatī*, or eloquence personified, is his consort. In the practice of the Hindu religion to-day *Brahmā* plays almost no part. *Vishnu* and *Śiva* have supplanted this too abstract god. But in the reform spiritual movement of the *Brahmo-Somāj* (q.v.), God is worshiped under the form of the ideal and supreme *Brahma*, which comprises the three manifestations of *Brahma*, *Vishnu*, and *Śiva*. Consult: Griswold, *Brahman* (New York, 1900); Löbbecke, *Ueber das verhältniss von Brāhmaṇas und Grāntasūtrien* (Leipzig, 1908); Milloud, *Le Brahmanisme* (Paris, 1905); Oman, *The Brahmins* (London, 1908); Tattvabhūṣan, *The Philosophy of Brahmanism Expounded with Reference to its History* (Madras, 1909). See INDIA; TRIMURTI, ŚIVA; VISHNU.

BRAHMAGUPTA, brā'mā-gūp'tā (born in 598). One of the most prominent Hindu mathematicians and astronomers. He wrote (628) the *Brahma-sphuta-siddhanta* (the 'Improved System of Brahma'), of which chaps. xii and xviii are on mathematics. Two other works by him are known, at least by title. *Brahmagupta's* mathematical chapters have been translated into English by Colebrooke (London, 1817).

BRĀHMAṆA, brā'h-mā-nā, THE. Second of the three grand divisions of Vedic literature, consisting of writings relating to prayer (*brāhman*) and sacrifice. These works, belonging to a much later period than the hymns, when the language had become obscure, represent the views of various teachers in regard to the interpretation of the text, the ritual, dogma, and the relation of the hymns to the sacrifice. In addition, a mass of legends, mythology, and speculations on philosophy and etymology produce a strange conglomerate, containing much that is absurd, but also much of value for the study of language and civilization. Attached to the *Brāhmaṇas* are two other classes of writing: the *Aranyakas*, containing instructions for the performance of the sacrifice by wood-dwellers, and the *Upanishads*. Of the preserved *Brāh-*

manas, the most important are the *Āitareya Brāhmaṇa*, attached to the *Rigveda*; the *Chandogya Brāhmaṇa*, with the *Chandogya Upanishads*; the *Ātharvaveda*, belonging to the *White Yajurveda*.

BRAHMANASPATI, brā'mā-nā-spāt'i. See BRIHASPATI.

BRAHMANISM, brā'man-iz'm, is the religion of the Brahmins, the priestly caste among the Hindus. Brahmanism professes to be the religion of the Veda (q.v.), and, as the Veda regulates the legal, social, and political life of the Hindus, the history of Brahmanism is to a large extent identical with the history of Hindu civilization. (See INDIA.) The present article is, however, mainly concerned with the religious aspect of Brahmanism. The roots from which the Brahman religion has sprung are numerous: magic practices, ancestral cult, belief in the soul and spirits were combined with theosophic and philosophic speculation and deliberate myth-making. These beliefs crystallized around a special ritual fostered by the Brahmins. The *Veda*, their holy writ, reflects therefore all these numerous and partly incongruous elements, and their import may be understood only in the light of the historic evolution of the Veda.

In a broader sense the *Veda* embraces the whole of the "revealed" or canonical literature of the Brahmins. With a more restricted meaning it applies only to the first four constituents of that canon, the *Rigveda*, the *Sāmaveda*, the *Yajurveda*, and the *Ātharvaveda*. The earliest of these is the *Rigveda*, which in some portions antedates considerably the first millennium B.C. It is composed of "verses," or "songs," containing invocations to the gods, many of which have great beauty, and is the earliest text written in an Indo-European tongue. The tenth and last book of the Veda is much posterior to the others—a fact which must be borne in mind if we wish to understand properly the trend of the religious development of India. The *Sāmaveda* consists almost wholly of stanzas borrowed from the *Rigveda* and arranged in the order in which they are chanted in the Soma sacrifice. The *Yajurveda*, too, is indebted to the *Rigveda*, but it also contains original formulas arranged in the order of various sacrifices. The *Ātharvaveda* is largely a collection of exorcisms and incantations against evil spirits. This Veda seems to have been adopted into the canon after some hesitation, and may mark the first concession made by the priests to the religion of the masses. These four metrical books constitute the Veda par excellence. Appended to each of these Vedas are other treatises, written in prose and purporting to explain the Vedic text and the ritual. Because they deal with prayer (*brāhman*), they are called *Brāhmaṇas*. They are considerably younger than the *Rigveda*, being written in an age when the four main castes had been already established. For this reason they lay stress on the importance of the Brahman and the sacrifice performed by him. The final portions of the *Brāhmaṇas* are called *Aranyakas*, or 'forest books,' since, owing to their peculiarly sacred character, these texts must be studied in the solitude of the forest. The final portions of these again constitute the *Upanishads*, or 'esoteric treatises,' and contain lofty metaphysical speculations on the nature of the soul of the universe (*Ātman* or *Brahma*). They are younger than the *Brāhmaṇas* and, from their position at the end of the Veda, are also called

Vedānta, a term which has come to mean the 'final goal of the Veda' and is also given to a school of pantheistic philosophy, which bases its teachings on the Upanishads. All the treatises thus far enumerated partake of revelation (*śruti*) and constitute the Veda in the wider meaning of the word.

Less authoritative than the Veda are a number of works viewed as embodying sacred 'tradition' (*smṛti*). These words are later than the Veda literature, being contemporary with the establishing of the Buddhist and Jain religions. In the first place come the *Sātras*, compendious manuals dealing with sacrifices (*śrauta-sūtras*), domestic rites (*grhya-sūtras*), or containing moral and legal commentaries (*Dharma-sūtras*). The last are the precursors of the *Dharma-sūtras*, which are still accepted as law in India, and the most famous of which is the code of Manu, or *Mānava Dharma-sūtra*. The two great epics, the *Mahābhārata* and the *Rāmāyaṇa*, also come under the head of *smṛti*, not only on account of their prodigious quantity of religious lore, but also because they are regarded as allegorical expositions of religious dogma.

The formation of the great popular religions of Vishnu and Śiva marked a new order in the spiritual history of India. The great epics and the old collections of religious lore, known as *Purāṇas*, underwent a revision in accordance with the new beliefs. The religious literature of India, instead of coming to an end, received a new impulse and led to the production of a tremendous mass of commentaries and super-commentaries, of allegoric and mythological poetry, and of philosophic treatises, all purporting, almost without exception, to be in agreement with the teachings of the Veda, but in reality connected with it by too slender a thread to deceive us. It is better to leave this literature out of consideration, since it reflects the spirit of modern Hinduism, and to consider as Brahman literature proper the Vedas and the *smṛti*. Accordingly we distinguish in this literature a Vedic and a post-Vedic age.

The gods (*devas*) of the Vedic period are personifications of the natural phenomena. No attempt was made at the outset to determine the relations of these divinities to one another. At a later epoch, however, a grouping was attempted, based on the threefold division of the Indian cosmos (*triloka*), and the gods were divided into three classes: (1) Celestial *Vasava* (the all-embracing heaven), the solar deities, *Aditya*, *Sārya*, *Savitr*, *Mitra*, *Pāśan*, *Vishnu*, who as yet was a minor god, and the goddess *Ushas* (the dawn), etc. (2) Aerial *Vāyu* (the wind), *Indra* (the lightning), *Rudra* (the thunder and father of the winds or *Maruts*), etc. (3) Terrestrial *Agni* (the fire), *Soma*, etc. Demons were known and feared, for instance, the dragon *Vṛtra*, enfolding the dark clouds, whom Indra strikes with his thunderbolt, *Vāta*, the goblins, *Rakshases*, etc. Among heroes peculiar importance attaches to *Yama*, who first discovered the way to the other world. The cow was held in reverence, and it has ever been considered a sacred animal in India. The Aryans also worshiped plants, such as sacred trees and, above all, the *Soma* (Avestan *Haoma*), the juice of which was drunk and offered in sacrifices. The cult of the ancestors required a perpetual domestic fire, before which rites were performed. The *Ātharvaveda* emphasizes incantations and exorcisms, in short,

magic or sorcery. As yet, although the souls of the dead are said to continue in the next world, in the land of *Yama*, there is no clear indication of the doctrine of retribution after death, and no evidence of the belief in transmigration, which was later destined to play a capital rôle in the history of the Hindu religion.

By what process did this polytheistic and naturalistic religion acquire the monistic and pantheistic traits of a later age? Several circumstances have contributed thereto. One of these was the tendency to establish the rudiments of a divine hierarchy, by assigning to one divinity in each of the three classes of gods a supremacy over the other deities of the same class. Thus the *Rigveda* already knows the triad *Sāya-Vāyu-Agni* (Sun-Wind-Fire). In the later Vedas and the Brahmanas, *Vāyu* was replaced by *Indra*, and in this manner the triad contained the three fiery elements of the sun, lightning, and fire. Now the fire had already been declared to be essentially one, despite the apparent multiplicity of terrestrial fires. From this to conclude that, in a certain higher sense, the three divinities were one, there was but a step. What led to this step is the further circumstance that the epithets and functions of the Vedic gods are more or less interchangeable and may be applied to several divinities. This tendency to identify the gods who present some points of similarity is frequently met with, *Agni*, for instance, being, in the *Rigveda*, expressly identified with *Indra* and *Varuna*. Free rein was thus allowed to the priests and poets to perceive the most far-fetched analogies, and in this way speculation influenced popular belief. Thus from the *Soma* juice being described as "celestial" and "brilliant" and compared in the sacrificial bowl with the moon in the waters, it was actually identified with the moon, and this belief was shared by the people.

A third factor which aided this line of thought is to be sought in the ease with which abstractions are personified in the Brahmanic literature. Thus we have *Aditi*, 'freedom', *Śraddhā*, 'faith', *Kāma*, 'love', *Brahma*, 'prayer', as independent divinities. Peculiarly adapted to this process are the *nomina agentia*, such as *Dhātṛ*, 'the creator, and the epithet applied to deities. Thus *Śiva*, 'auspicious', an epithet of *Rudra*, became the name of a god, other epithetic names are *Prajāpati*, 'lord of creatures', *Brhaspati*, 'lord of prayer', both important names in the history of Brahmanism. The occasions for the identification of the gods were thus multiplied, and when one of these divinities was hailed as the absolute, the others could be simply considered as predicates of the chief divinity. The idea of the gods' being but various names of a unique supreme being is expressed in the famous "creation hymn" of the tenth book of the *Rigveda*. At the origin, it is there said, "there was neither death nor life, neither night nor day, appeared. The One breathed calm and windless, and beyond it there was no other being." This doctrine received additional strengthening in the *Āraṇyakas* and the Upanishads.

A pantheistic tendency contended for supremacy with the monotheistic. The seven cosmogonic hymns of the same book of the *Rigveda* describe generation as a development, or unfolding, of the universe from a divine being called *Purusha*, 'self or man'. *Prajāpati*, 'lord of creatures', *Viśvakarman*, 'the all-maker', and *Hvanyagarbha*, 'the golden embryo'. While

these divinities were by some regarded as representing the same deity under various aspects, others identified the world with God, or spoke of Puruṣa as the cosmic soul, or universal Ātman. The monotheistic tendency is visible chiefly in the Brāhmaṇas, whereas pantheism finds expression in the Upanishads. But the same divinities are at times understood in a monistic, at others in a pantheistic sense. Thus *Puruṣa*, 'the self,' or the primeval man-giant, of the Rigvedic "Hymn of Puruṣa," is also declared to be "all this world, what has been and shall be." In the Brāhmaṇas he is identified with Prajāpati, the personal creator and lord of the third world, while in the Upanishads he is said to be the same as the universe, Ātman. In the Sankhya philosophy Puruṣa is the 'soul' as opposed to 'matter.' A similar history obtains for Ātman ('breath,' afterward the 'cosmic soul'), which was identified in the Upanishads with Brahman. It was this god who was destined to reconcile the conflicting monotheistic and pantheistic tendencies of the later Vedic speculation, although how far this reconciliation goes is a matter of individual opinion.

Already in the Rigveda we find three classes of priests: the reader (*hotr*), the singer (*udgātṛ*), and the officiating priest (*adhvaryu*). The Vedic word for both worshiper and priest is *brāhmān* (masculine; nom. Sing., *brāhmā*), and is in this sense found 46 times in the Rigveda. There is as yet little indication of a special caste of Brahmins, the word *brāhmaṇa*, 'man of the first caste' occurring only eight times. The Vedic 'prayer' or 'formula' is also *brāhmaṇ* (neuter; nom., sing., *brāhmā*). The word *brāhmā* also means 'devotion, worship,' in the abstract sense and also 'the sacredness of *brāhmān*,' as manifested in priest and prayer. This sacred character of prayer was personified and worshipped under the name of *Bṛhaspati*, 'lord of prayer.' This god followed the evolution of his earthly representative, the Brahman priest, and as it became customary for rājās to have a chaplain or *purohita* to perform the sacrifices, the god *Bṛhaspati* became the *purohita* and the teacher (*guru*) of the gods. But even this god was destined to give way to a personification of Brahman (*Brāhmā*), which retained for the god this very name.

The word *brahma* connotes a 'magical power' lurking behind prayer or sacrifice; by means of prayer or sacrifice the gods are not so much requested for assistance as actually compelled to do the bidding of the officiating priest. From this stage there is but a step to another, in which the word *brahma* is conceived to include the all-pervading power of sacrifice, hence 'universal order' or 'holy rule.' "Through Brahman (formula) are heaven and earth held together," therefore Brahman rules the world. The god Brahman was therefore recognized. In the Brāhmaṇas this divinity was fully established, and in the Upanishads it is identified with the vital principle which permeates the universe (Ātman). We are thus brought to face a divinity which, under the same name, has a double function. Under one aspect it is impersonal (*brāhmā*, neuter) and designates the 'universal power of prayer and sacrifice'; from another point of view it is personal and designates the ruler of the universe (*Brāhmā*, masculine). Nothing more natural than to identify the two and, this being done, to fuse around this divinity the attributes and functions of Puruṣa,

Ātman, Prajāpati, Bṛhaspati, and the other ruling and creative deities. When the doctrine of transmigration came to be firmly rooted in the Hindu mind, *Brāhmā*, the god in the personal aspect, was regarded as an incarnation of *Brāhmā*, the impersonal divinity. Speculation as to the nature of Brahman took also another direction: As the individual breath or ātman is but a particle of the cosmic Ātman, the Brahman worshiper became a part of divinity. Says the Chhāndogya Upanishad, in speaking of the Ātman: "This whole world consists of it: that is the Real, that is the Soul, that art thou (*tat tyam asi*).'" And the *Bṛhadāraṇyaka* says: "whoever knows this 'I am Brahman' (*Aham brāhmāsmi*) becomes the All. Even the gods are not able to prevent him from becoming it. For he becomes their self (Ātman).'" When the doctrine of the transmigration of the soul became an all-admitted truth, when in consequence thereof the incarnation of the gods became one of the firmest tenets of Hindu belief, the barriers between men and the gods did no longer look impassable, and the Hindus believed that, through the instruments of doctrine, sacrifice, conduct, or asceticism, they could be raised to the rank of divinities and thus approach the final goal of Hinduism, the loss of individuality in the all-pervading Brahman or, as with the Buddhist, in the Nirvāṇa.

The code of Manu relates that the universe lay in a chaotic state; differentiation was brought about by the divine spirit or intelligence; this created the waters by meditation, and, from this water impregnated with the divine force, sprang out the *Hiranyagarbha*, or 'golden embryo,' which is already mentioned in one of the Rigvedic hymns. From these the male *Brāhmā* was born, the progenitor of all beings. He is therefore both *Śvayambhū* ('self-born') and *ajā* ('unborn'). It took centuries to accomplish this evolution of the divinity *Brāhma*, and the code of Manu, in which a definitive place was assigned to Brahman in the Hindu cosmogony, is posterior to the advent of Buddhism and marks the final step in the history of Hindu caste (*varṇa* or *jāti*).

A few words are necessary in connection with the history of the Brahman caste. When the Aryan people settled in India, the well-known division into *Brāhmins*, or priests, *Kṣatriyas*, or warriors, and *Vīśas* (*Vaiśyas*), or merchants and agriculturists, was not a hard and fast one. The consciousness of forming one Aryan people must have held these classes together and reminded them of the necessity of uniting their forces against the dark-skinned native populations of India (*Dāsas*). The word for caste in Sanskrit is *varṇa*, 'color,' and it is likely that the term was first used to distinguish the Aryan from the non-Aryan. The *Vaiśyas* were the whole people as opposed to the aboriginal *Dāsas* or *Dasyus*. Just as to-day the members of the Brahman caste may, and do, exercise any of the "clean" professions, it is possible that originally the Aryan householder might, if he wished, choose the profession of arms, or priesthood, or agriculture, as a means of livelihood. There is nothing in the early Vedic literature to make it certain that marriage with the lower classes of society was forbidden. But towards the end of the Vedic age a change came into being. The aboriginal populations which were thrown into submission by the Aryans were considered as forming a caste of serfs (*śūdra*), which it was

dishonorable for the Aryans to enter. At the same time the differentiation between the priests and the Vaisyas became more marked, and the priests were led to consider themselves superior to the rest of the people and to form a caste of their own. The Vaisyas were to serve both Brahmins and Kshatriyas. This situation is, to a certain extent, paralleled by the division into patricians and plebeians which obtained in ancient Rome. It is probable that their example was followed by other groups of people, as castes and subcastes are now numbered by the hundreds in India, and new castes are formed under our very eyes, being determined by descent, nationality, occupation, and change of occupation, crossing, migration, religion, and other factors of secondary importance. Although there is a nice gradation in the relative situation of the various castes, and despite the fact that the lower castes show consideration to the higher, an esprit de corps binds together the members of the same caste, who are just as jealous of their own privileges as the Brahmins are of theirs. The early portions of the Rigveda know of no sharply drawn caste divisions. It is in the *Purusha Sūkta*, or 'Hymn of Purusha' (*Rigveda*, x, 90), that mention is made of the four main castes, *Brahmanas* (priests), *Rājanyas* (warriors), *Vaiśyas* (agriculturists), and *Sūdras* or seifs, as having respectively sprung from the mouth, the arms, the thighs, and the feet of Purusha. In the *Brahmanas* and the *Sūtras* we are able to follow the progress of the Brahman caste which was definitively sanctioned in the code of Manu.

In the Vedic age the organization of society was patriarchal, and consisted of families united in class, under the rule of a king or rāja. The head of the family had full power over the other members. In the clan (*gotra*) intermarriage was forbidden, and when the caste system was fully established no marriage was legal outside of one's own caste, but girls could marry into superior castes, their progeny would belong, however, to a mixed caste. The great religious function of marriage was to continue the family rites (*samśkāras*). The most important of these rites is the *upanayana*, or religious initiation. When he reached the proper age, the boy of the three upper castes had a sacred cord wound over the left shoulder and under the right arm and was conducted to a *guru*, or teacher of the Veda and the rites. After being initiated, he was expected to invoke the sun every morning and evening, in a prayer called *Sāvitrī*, and this ceremony was considered to be equivalent to a rebirth or spiritual bath. It is for this reason that the members of the three upper classes are called *dvijas*, 'twice born.' Other important rites are those of expiation, of marriage (*vivāha*), death, and the cult of ancestors (*śrāddha*). When the bridegroom led the bride from her father's house to his own home, he also brought the fire which was used for the marriage ceremony and thus established his own domestic fire. Before this fire (*gāhapatya*) were performed the rites and the five daily offerings. Other rites are of a ceremonial nature and call for the employment of several Brahmins. The most frequent of these *Śrauta* rites is the *Soma* sacrifice. Another is the *asvamedha*, or horse sacrifice. These rites are beyond the means of the poor, and, through the remuneration and honor they brought to the priests, they have contributed more than any-

thing else to the elevation of the Brahman caste. The *Sudras* are, of course, excluded from the performance of sacrifices, and they cannot even meet a Brahman without contaminating him. For the Brahman who wishes to attain beatitude, the following course of life is laid out. From the time of initiation to marriage he is to be a *brāhmachārin*, or religious student, upon marrying he enters the stage of *gṛhastha* (*gṛhapati*), or householder. When the householder 'perceives his skin to have become wrinkled and his hair gray, when he sees the son of his son,' he is ripe for the stage of *vanavāsin* (*vanaprastha*), or anchoite. When he has succeeded in extinguishing all earthly passions, he is to enter the condition of *bhikṣu*, or religious mendicant. This course of life lay also open to the other twice-born men.

Brahma has always preserved the mark of his origin in a priestly abstraction. He never became a popular god, just as his religion remained that of a privileged caste and not a universal religion, like Buddhism or Jainism. Brahma was regarded as an imperturbable divinity who held aloof from this world, while the real divine agencies governing this world were to be found in Vishnu, Śiva, Kṛṣṇa, Devī, and other popular gods. The *trīmūrti*, or Hindu Trinity, Brahma-Vishnu-Śiva, which appeared in the fifth century A.D., seems to be a compromise by which the Brahmins placed their god at the head of the two modern Hindu divinities in order to insure his nominal supremacy, while the other two godheads were to be the actual rulers of the world. In this way Brahman theology was enabled to consider Vishnu and Śiva as emanations of Brahma, but other beliefs acknowledge a duality (Vishnu-Śiva or Hari-hara), or even an identity of the two gods.

The time when these two divinities began to have a cult of their own is not known. But very likely this happened before the apparition of Buddhism and Jainism. The epic and the Purānas testify that these cults were old at the time of their redaction. In the third century B.C. the Greek Megasthenes, who has left a description of India, tells us that the cult of Dionysos (Śiva), the more ancient of the two, had flourished chiefly in the mountains, whereas the inhabitants of the plains adored Herakles (Vishnu).

These two great divinities are not unknown to the Veda. Vishnu is mentioned a few times in the Rigveda by his very name, and is a personification of the solar luminary, which in its daily course traverses the three worlds with three steps,—a metaphor which proved the starting point of the doctrine of *avatāras*, or divine incarnations under various forms. He assumed a more prominent position in the Yajurveda, in which he is constantly identified with the sacrifice. Śiva, 'the auspicious,' is the epithet given in the Rigveda to the terrible Rudra, the 'roaring' thunder god and the father of the winds or Maruts. That epithet was given for fear of vexing this terrible divinity, whose malevolent character has been retained in Hinduism. The Yajurveda knows him as Śiva, and in the Epic his importance is such that he is called *Mahādeva*, the great god. Śiva is also god of generation and seems to be in this respect a continuation of the Vedic Pūshan. One of his attributes is the phallus (*liṅga*), which is the object of a widespread worship. In his festivals dramatic performances took place, Śiva having

come to be considered, under the name of Ganeśa, the god of drama.

The post-Vedic divinities are distinguished from their Vedic predecessors by several traits which have largely their origin in the Veda, but which attained full development in the subsequent epoch. The most obvious of these traits is the anthropomorphic and individualistic character of the gods, each of which has a shape, attributes, and a biography of his own. As a partial offset to this we meet with another trait, which originated in the curious admixture of pantheism which we already noticed, but which now takes the form of the doctrine of incarnation. According to this view, while each divinity possesses its own individuality, it may nevertheless be an incarnation of one of the higher gods, Vishnu or Śiva. In this way local cults can subsist side by side. The avatāras, or incarnations of Vishnu, are peculiarly important, the Mahābhārata knowing no less than 1000 names of this divinity, which may be considered his incarnations. The most popular of Vishnu's incarnations is *Kṛṣṇa*, the 'black god,' the chief deity of the *Bhāgavata-Purāṇa*; other incarnations are *Arjuna*, the hero of the Mahābhārata, and *Rāma*, the hero of *Rāmāyaṇa*; *Vāsudeva*, etc. The famous poem *Gītāgovinda* sings the love of Kṛṣṇa for the beautiful cowherdess *Rādhā*. This example found many imitators, for the doctrine of incarnation easily lends itself to poetic elaboration; and poetic mythology and allegory may be considered as characteristic of the post-Vedic age. The obscurity of many of these legends did not detract from their popularity.

Female divinities were known in the Vedic age, but the Vedic goddesses do not have the prominence of their male companions. In the post-Vedic age it became the rule to associate a female deity (*śakti*) with each male god. Vishnu's companion is the gracious *Lakṣmī*, or *Śrī*, the goddess of beauty and wealth, while the consort of Śiva is known by several names, such as *Rūdrānī*, *Uṃdā*, *Bhairavī*, *Kālā*, *Pārvatī*, *Durgā*, *Kālī*, or simply *Devī*, and is even more wicked than her husband. Brahma himself is associated with *Vāch*, or *Sarasvatī*, the goddess of speech, learning, and understanding. The Vedic divinities, although not so popular as the new deities, continued to be invoked in prayers, since the Vedic texts or *mantras* and the ritual connected with them were retained. An elaborate mythology made up for their loss in popularity. The eight more prominent were called *Lokapālas*, 'world guardians,' and were assigned to preside over the cardinal and the intermediate points of the compass: *Indra*, their chief, over the east; *Agni*, over the southeast; *Yama* over the south; *Sūrya* over the southwest; *Vāruṇa* over the west; *Vāyu* over the northwest; *Kubera* over the north; and *Soma* (or *Chandra*) over the northeast. The abode of these gods is the heaven of Indra, the middle world (*svarloka* or *svarga*). At the same time some of the old gods underwent a change in function, and a host of new divinities shared with them the Hindu pantheon. *Kāma*, the old love god, is represented with bow and arrows of flowers and bowstring of bees. The sacred river Ganges was worshipped as the goddess *Gāṅgā*. *Yama*, the Vedic King of the dead, has now become the god of the lower world and the judge of the dead. *Skanda* is the general of the celestial armies. *Ganeśa*, the son of Śiva and Pārvatī,

has the head of an elephant and is the god of wisdom; *Dharma* was the god of justice, etc. Demigods are numerous, such as *Nārada*, the messenger of the gods; the *Gandharvas*, the heavenly musicians, already known to the Rigveda; the fair *Apasaras*, scarcely mentioned in the Rigveda, whom Indra employs to seduce the holy men that threaten his supremacy by their ascetic exercises; the malicious *Rakshases*, etc. The demons of this epoch (*Asuras*, *Datyas*, *Dānavas*) are very numerous and wicked. Serpents (*Nāgas*) were adored, and the sacred character of the cow was established beyond doubt. A mythological cow, the *Kāmaduhī*, or cow of plenty, is frequently alluded to in literature. Bulls were dedicated to Śiva in his capacity of god of generation. Statues and images of the gods were reverently worshipped. The men who excelled in piety were revered as saints; and this reverence was extended to their works or relics.

The new beliefs, unknown to the Veda, are quite common in the post-Vedic age: the doctrine of the transmigration (*samsāra*) of the soul and the doctrine of *Karma*. The latter holds that the consequences of one's actions are not destroyed by the death of that individual, but still persist and determine the fate of the soul in the other world. This idea was connected with the belief in the soul's persistence after death and the doctrine of transmigration took shape. In the Upanishads it is said that the righteous ascetic, who, moreover, possesses the right knowledge, enters after his death the "path of the gods" (*devayāna*), which finally leads to absorption in Brahma, while the householder who has performed right sacrifice enters the "path of the fathers" (*pitryāna*) and dwells in the moon until his *karma* is worked out. After this he is born again in this world, first as a plant and afterward as a man of the three higher castes. The wicked are born again as outcasts or unclean animals. By the time of the Epic this belief was universal. (See BUDHISM; METEMPSYCHOSIS.) With the belief in transmigration was associated the belief in hell, where the wicked are punished for their evil deeds.

Pilgrimages, sacrifices, expiatory ceremonies, exorcisms, incantations, and all kinds of magic practices were very common in this period. The cremation of widows (*sati*), which was not known in the Vedic time, became a sanctioned practice, as the wife's position in the family diminished in influence.

Pursuant to the belief in transmigration, the idea was entertained that man is not radically different from the gods, but that man and god are both steps in the infinite scale of beings, the gods being nearer the final goal (Brahma). Far from believing that our world was the only reality, many held that it is a mere illusion (*māyā*), which it is better to dispel. To shorten the *samsāra* and thus to come nearer the final rest became the transcendent purpose of our life. The Hindu sought deliverance or "enlightenment" (*mukti*, *moksha*) in various ways, some believing in the efficacy of rites and expiatory ceremonial, others in asceticism and self-chastisement (*yoṅa*), others still in the possession of true knowledge and the freeing of the soul from all desire, while the mystics sought deliverance in the love of god (*bhakti*). In their pursuit of deliverance the followers of Buddha and Mahāvīra left the narrow religion of the Brahmans

for the universal religions of Buddhism and Jainism. Between the amoral god of the Brahmins and philosophers and the immoral gods of the people the thinking Hindu could not reach a satisfactory choice. A few superior spirits among the Brahmins, like the great Śaṅkara Acharya, perceived this and inaugurated a movement of religious reform which has enabled Brahmanism to hold its ground to our time. See HINDUISM.

BRAHMAPUTRA, bra'ma-puṭra (Skt. *Brahma* + *putra*, son, offspring). A river of Asia, rising as the Sampo, on the table-land of Tibet, in about lat 30° 30' N and long 82° E. Its source, which is near to the headwaters of the Sutlej and Ganges, lies at an elevation of nearly 16,000 feet. The stream takes a general easterly course to beyond the 94th meridian, when, as the Dihong, it is deflected southward, traverses the Himalayas, and enters upon the lowland plains of Assam. Its identity with the Sampo and Dihong, though long undoubted, was not actually demonstrated till 1913. Shortly after leaving the mountains it receives from the east the Lohit or Brahmakunda, which was for a long time considered to be the main river. In lat 25° 10' N and long 89° 43' E. it throws off the Konaie, and after a course of 180 miles is named the Megna. Ninety miles from the sea it combines with the Ganges in cutting up their common delta into a network of inland navigation. A regular steamer service is maintained between Calcutta and Dibrugarh, 800 miles up the river, and vessels of large burden can ascend as high as Gauhati. Total length, about 1800 miles. Consult Williamson, "The Lohit-Brahmaputra" in *Geographical Journal* (London, 1909).

BRAHMO-SOMAJ, bra'mō-sō-maj', or, better written, BRAHMA-SAMAJ (Hind. *Brahma*, Skt. *Brahmā*, *Brahma*, prayer + *samaj*, assembly for worship) (*Theistic Church*). A religious and social association in India, originated by the cele-

brated Hindu Rajah, Rammohun Roy (q.v.), in 1828, under the title "Society of God." At first the service of the society was divided into four parts: the recitation of texts from the Vedic hymns, the reading and translating into Bengali of passages from the Upanishads, the delivery of a sermon in Bengali, and the singing of hymns accompanied with instrumental music. Only Brahmins were allowed to lead in the service. The conversion of Debendra Nath Tagore, a rich Brahman of Calcutta, in 1841, gave the movement a strong impetus, which, with the spread of English education, succeeded in emancipating it from Vedantism. The third stage in the development of the Brahma-Somaj took place under Babu Keshub Chunder Sen, who joined the church in 1857. The aim of Sen and his followers was to apply the principles of the sect to practical every-day life, and under his direction the more progressive members withdrew from the original organization and formed the "Brahmo-Somaj of India." Their fundamental beliefs are as follows. That there is but one supreme God, the object of worship, that nature and reason are the sources whence we derive our knowledge of God, and that religion allows progressive development. They have renounced all the distinctions of the caste system with which India has so long been fettered, and they consider all men as equally the children of God, they have given up all the old Vedic and Brahmanical sacrifices, they believe in no sacred books or places, but accept whatever is true and good in any religion. In 1880 there were 149 *somajes* scattered throughout India, and of these 44 have *mandirs*, or places of worship. They have established schools and have published at different times 18 periodicals, of which 6 were in English, 9 in Bengali, and 3 in minor vernaculars. They have reformed the abuse of child marriage and have done much to promote female education. In 1878 some of Sen's followers who disapproved of certain of his tenets, and of his conduct in marrying his daughter at the age of 13 to a Hindu maharajah, seceded and formed the Sadharan (or Universal) Brahma-Somaj, which soon took the first place among the theistic churches of India. Their creed was the same as that of the original Somaj with the addition of the following articles: the brotherhood of men, the immortality of the soul, and that the punishments of God are remedial and not eternal. The Arya-Somaj, founded by Dayananda Sarasvati (died 1882), differs from the Brahma-Somaj in considering the Vedas as divine revelation in which everything true and useful, even the recent discoveries of science, could be found. Consult *Brahmo Dharma, or Religion of the Brahmos* (1850), Keshub Chunder Sen, *Indication of the Brahma-Somaj* (Calcutta, 1860), Ghose (editor), *Works in English of Rammohun Roy* (2 vols., 1885-87), *The Autobiography of Maharshi Devendranath Tagore*, translated from the Bengali by Satyendranath Tagore (Calcutta, 1900), F. Lillingston, *The Brahma-Somaj and Arya-Somaj* (London, 1901), Mozoomdar, *Life and Teachings of Keshub Chunder Sen* (Calcutta, 1887), F. Max Müller, *Ramānirishma His Life and Sayings* (New York, 1899), id., *And Lang Syne, Second Series* (New York, 1899), and the *Theistic Quarterly Review*, the official organ of the Brahma-Somaj, published in Bengal since 1880.

BRAHMS, brāms, JOHANNES (1833-97). One of the supreme masters of music. His grandfather had been a carpenter, and his grand-

father an innkeeper. The latter's second son, Johann Jacob (1806-72), early showed a decided talent for music, which he cultivated in spite of his parents' opposition. In 1826 he settled in Hamburg, where for many years he played the double bass in the orchestra of the Stadtheater. In 1830 he married Johanna Nissen. Of this union three children were born, of whom Johannes, born May 7, 1833, was the second.

The elder Brahms regarded it as a matter of course that his son should follow the profession of music, and accordingly Otto Cossel was chosen as a teacher. The boy's talent was so evident and his progress so rapid that at the age of 10 he was placed under the instruction of Eduard Marxsen, at that time the foremost musician of Hamburg. That his creative talent must have manifested itself with extraordinary power we may gather from Marxsen's words when he heard of the death of Mendelssohn: "A great master of music has passed away, but a greater one will arise in Brahms." This was in 1847. In the same year the boy made his first public appearance as a pianist, but he still continued his studies under Marxsen. Unfortunately nothing has been preserved of his earliest compositions. In all probability Brahms destroyed them, as he later on always burned compositions which he did not think worthy of publication.

When in 1853 Remenyi (q.v.) visited Hamburg, Brahms joined him for a concert tour, appearing as accompanist, soloist, and composer. Whatever plans the young men may have had, they were suddenly changed by the meeting with Josef Joachim (q.v.) in Göttingen. The great violinist was so deeply impressed both by the playing and the compositions of Brahms that he recommended him to Liszt (q.v.) in Weimar, where the young musician spent six weeks as Liszt's guest. But in spite of his host's amiability Brahms did not find the musical atmosphere of Weimar congenial, and he returned to Göttingen to Joachim. In the beginning of October, 1853, Brahms, bearing a letter of introduction from Joachim, called upon Schumann in Düsseldorf and played for him the works in manuscript now known as op. 1, 2, 3, 4, 5. Before the month was out there appeared in the *Neue Zeitschrift für Musik* Schumann's famous essay, "Neue Bahnen." But that was not all. The article was immediately followed by an enthusiastic personal letter to Breitkopf and Härtel, the result of which was the publication by that famous firm of Brahms' Sonata in C, op. 1; Sonata in F♯m., op. 2; Six Songs, op. 3; Scherzo in E♭m., op. 4. Almost simultaneously B. Senff published the Sonata in Fm., op. 5, and Six Songs, op. 6.

One might think that after such an introduction Brahms would have no difficulty in gaining recognition. Quite the contrary is true. All musical parties assumed an attitude of critical reserve. Only the immediate circle of Schumann's friends and admirers—and very small it was at that time—accepted the newly proclaimed genius.

During Schumann's lifetime Brahms remained in Düsseldorf, devoting himself with all the earnestness of his serious nature to the study of the works of the great masters, especially Bach. But he also composed diligently, although for some years nothing new of the much-heralded new prophet appeared in print. In 1857 Brahms accepted an offer from the Prince of Lippe-Detmold. As director of an excellent chorus he

there gained that practical and intimate knowledge of choral singing which later on he utilized in the writing of his monumental masterpieces. He also completed his first concerto for piano and orchestra in D minor, op. 15. The first performance took place in Hanover, Jan. 22, 1859, with the composer at the piano and Joachim directing the orchestra. It was received with icy coldness. Five days later Brahms played it in the Gewandhaus in Leipzig. On that occasion the composer and his work were hissed. Undaunted by this failure, the master, together with Joachim and Stockhausen, appeared in the same year in his native city, where the same concerto and his first serenade for orchestra in D, op. 11, were received with enthusiasm. In the following year, 1860, he visited Hamburg again and produced two new works, the second serenade in A, op. 16, and those exquisite choruses for female voices with accompaniment of horns and harp, op. 17. The favorable reception accorded also to these works induced Brahms to resign his position in Detmold. For the next two years he again lived in Hamburg, although he spent much of that time making tours in Switzerland and along the Rhine.

In September, 1862, Brahms paid his first visit to Vienna. His success as pianist and composer was instantaneous, so that the conductorship of the famous Singakademie was offered to him, a post which he accepted. But before his three-year contract expired, he resigned and resumed his free, roaming life. The years from 1864 to 1868 he spent traveling about, indulging his favorite pastime of making extended foot tours, and stopping for longer or shorter periods at Baden-Baden, Winterthur, Karlsruhe, Zürich, and Bonn. In Zürich he met the celebrated surgeon Billroth (q.v.), a passionate lover of music, who became one of Brahms's most intimate friends and subsequently played an important part in his life. But while he thus indulged his passionate love for nature and travel, the master was not idle. It was during these years that he wrote, besides many other masterpieces, the work which first gained him general recognition, *Ein Deutsches Requiem*, op. 45, the score of which was completed in 1866. Three movements were performed in Vienna in 1867, but the first performance of the entire work took place under the direction of the composer in the cathedral at Bremen, April 10, 1868. The impression produced was so overwhelming that the work was not only repeated in Bremen 10 days later, but it made the rounds of the principal German cities. What Hanslick (q.v.) wrote at that time is still true today. "Since Bach's Mass in B minor and Beethoven's Missa Solennis nothing has been written in this field that can be placed by the side of Brahms's German Requiem."

Long before this the Wagner partisans had assumed an attitude of open hostility. Now all the enemies of Wagner flocked to the standard of Brahms. Personally, the master not only never sympathized with, but emphatically discouraged all attempts to set him up as an "anti-pope." He was, however, a close student of Wagner's scores and an ardent admirer of his genius. Brahms was one of the most profound musical scholars of his time. He knew everything that had been written before him, and he knew from personal study the works of all his important contemporaries. Besides this, he was a profound student of literature and history. When this is taken into account, together with the severely

critical attitude which he took toward his own compositions, it explains the comparatively small number of works produced during an active life extending over 64 years. At the same time it explains the uniform excellence of these works.

In the meantime Vienna had come to regard Brahms as her own. The influential critic, Dr Hanslick (qv), had been indefatigable in making propaganda for the master, and a small but truly appreciative circle of admirers brought it about that in 1872 the conductorship of the *Gesellschaft der Musikfreunde* (qv) was offered to Brahms. Rather reluctantly—for he knew he was not a great conductor—he accepted, and directed the concerts for three seasons. It was the last time that the master held an official position. After that Brahms devoted all his time to composition and his favorite studies. The revenues he derived from the sale and performance of his works were such that he could gratify all his simple tastes and lay aside a considerable fortune. In 1867 Billroth had settled in Vienna, and here his hospitable house soon became the centre of a select musical and artistic circle, whose special privilege it was to hear the first performance of all new works of Brahms before they appeared in print. The orchestral works were performed on two pianos, Brahms playing the first and Brüll (qv) the second. The summer months the master always spent in the country or traveling, the winter months in Vienna. For a quarter of a century this was the regular order of things. Henceforth the history of Brahms is the history of his works.

After the year 1877, when the master's first symphony appeared, all serious opposition was swept away. Only the extreme Wagner partisans continued their attacks. Bulow (qv), one of the most ardent, but sane, advocates of Wagner, now came forward as the equally zealous champion of Brahms. It was after the study of this symphony that Bulow originated his famous phrase of the "three great B's" (Bach, Beethoven, Brahms). On his triumphal tours with his celebrated Meiningen Orchestra he conducted all the great orchestral works of Brahms, and as a pianist played the two piano concertos in D minor and B flat. In this connection it is interesting to note that three other great conductors who worked indefatigably for the recognition of Brahms—Levi, Richter, Wüllner—were at the same time fighting the battle for Wagner. Every year Brahms gave the world at least one immortal masterpiece. Honor after honor was showered upon him. King Ludwig of Bavaria decorated him in 1874 with the Order of Maximilian, on the same occasion on which he conferred this distinction upon Wagner. The Berlin Academy of Arts elected him a member. The Universities of Cambridge and Breslau conferred upon him academic degrees, *honoris causa*, in 1877 and 1881 respectively. This honor on the part of the German institution Brahms acknowledged by the dedication of his *Akademische Festouvertüre*, op. 80. In 1889 the Senate of his native city elected him "honorary citizen," for which distinction the master sent the burgomaster the *Fest und Gedenksprüche* for eight-part chorus a cappella, op. 109. In the same year he was decorated with the Austrian Order of Leopold, and in 1896 with the medal for Arts and Sciences. On the occasion of his sixtieth birthday the *Gesellschaft der Musikfreunde* struck a gold medal in his honor.

Brahms's health had always been robust. During his whole life he had never known a

day's sickness. During the summer of 1896 some friends who visited the master at his summer home in Ischl were shocked at his appearance. His figure seemed to have shrunk, his skin was yellow, his expressive eyes had lost their lustre. The doctors correctly diagnosed the case as degeneration of the liver, but kept the seriousness of the disease from their patient. A treatment at Karlsbad brought only temporary relief. When, in the fall of 1896, Brahms returned to Vienna, he was much weakened. Nevertheless he would not hear of being sick and forced himself to appear among his friends and at concerts. On March 7, 1897, he was seen for the last time at a concert. His own Fourth Symphony was the principal number, and the revered master was forced to respond to the insistent calls from the audience. On the 24th he went out for the last time to dine with friends. After that his weakness increased so much that he was obliged to keep his bed. His devoted landlady and a few intimate friends remained in constant attendance until at 9:30 in the morning, on April 3, 1897, the great master closed his eyes forever. In the Central Cemetery of Vienna, opposite the grave of Beethoven and close by the side of Schubert, the mortal remains of Brahms were consigned to their last resting place.

In 1906 the Deutsche Brahmsgesellschaft was founded in Berlin, the object of which is the publication of books relating to Brahms. So far it has published the master's correspondence and the comprehensive biography by Max Kalbeck.

A Instrumental Works for Orchestra
First of all stand those four colossal symphonies, which can be compared only with the four greatest symphonies of Beethoven. The first in C minor, op. 68, was not given to the world until the year 1877, after the master had passed his fortieth year and was recognized as unsurpassed in all the fields he had cultivated up to that time. He knew what was expected of him as a symphonist, and, above all, he knew what he exacted of his own genius before taking the final step that was to place him on the highest pinnacle of his art by the side of Beethoven. Accordingly, as an experiment and by way of preparation, he wrote in 1873 those masterly variations on a theme of Haydn, op. 56. As Brahms had foreseen, friends and enemies immediately compared his first symphony with Beethoven's ninth—the latter to demonstrate Wagner's assertion that Beethoven had exhausted the form of the symphony, the former to demonstrate the contrary. But the overpowering grandeur of the themes, their masterly development, the noble intensity and majestic symmetry of the whole work assured the immediate triumph of Brahms. Bulow characterized it as the "Tenth Symphony." Following his usual custom of always entering upon a new field with two compositions in close succession, Brahms produced his Second Symphony in D, op. 73, in the following year, 1878. The success of this work even eclipsed that of the first symphony. The chief reason for this more enthusiastic reception is to be found in the fundamental mood of the two compositions. The first is severe, almost tragic, though it ends with a hymn of triumphant victory, the second is reposeful and breathes a spirit of unalloyed joy. The first discloses its beauties only after study or repeated hearing, the second makes an immediate appeal. Six years later, in 1884, the Third Symphony in F, op. 90, followed. Here the master again strikes more passionate ac-

cents. The irresistible sweep of the very beginning immediately carries the listener away and holds him spellbound. The Fourth Symphony in E minor, op. 98, appeared in 1886. In spite of the simplicity of its structural lines and the perspicuous grouping of its themes it is the one most difficult to penetrate. It fails to make an immediate appeal because of its austere character and the profusion of detail. Especially the finale appeals to the layman a hopeless puzzle. But it is nothing else than one of the older forms cultivated by Bach, the chaconne (q.v.), which no one expects to encounter in a symphonic movement. Brahms uses an eight-bar theme, which throughout the movement he holds as a basso ostinato (q.v.) over which the other instruments execute a series of variations.

The two beautiful serenades for orchestra appeared in 1860. The first, in D, op. 11, consisting of seven movements, is scored for full orchestra; the second, in A, op. 16, has only five movements and is scored for small orchestra. The form is one extensively cultivated by Haydn and Mozart. See SERENADE.

The *Academische Festouvertüre*, op. 80 (1881), is a work in strict form, built entirely upon well-known student songs for its thematic material. A marvel of contrapuntal skill, it nevertheless is full of rollicking jollity and exquisite humor. The *Tragische Ouvertüre*, op. 81, belongs to the same year. It delineates no definite programme, but portrays in masterly fashion the tragic mood.

For solo instruments with orchestra Brahms wrote two concertos for piano and orchestra in D minor, op. 15 (1859) and in B♭, op. 83 (1882). In reality both are symphonies with piano obligato. The solo instrument never predominates; it is intentionally treated as an integral and essential factor. Yet the demands made upon the mere technical equipment of the performer are enormous, while the musical content is beyond the interpretative powers of any but the greatest artists. The same is true of the concerto for violin and orchestra, in D, op. 77 (1879), which by many is regarded as the greatest violin concerto in existence. The double concerto for violin and violoncello and orchestra, op. 102 (1888), is one of the most difficult to appreciate of all the master's works. It is really a *concerto grosso* (q.v.) on a gigantic scale.

B. Chamber Music. Had Brahms written nothing but his imperishable masterpieces in the field of chamber music, he would still be immortal. Here he also surpasses all other masters, except Beethoven, and even the latter when we consider the variety of the combination of instruments. It was reserved for Brahms to show the possibilities of the horn and clarinet in combination with the instruments which ordinarily are regarded as best suited for chamber music. To speak of any of these works in detail would exceed the limits of this article. A mere enumeration must suffice. Three string quartets in C m. and A m., op. 51; B, op. 67. Two string quintets, F, op. 88; G, op. 111. Two string sextets, B♭, op. 18; G, op. 36. Quintet for pf, 2 vls, vla, vc, F m., op. 34. Three quartets for pf, vl, vla, vc, G m., op. 25; A, op. 26; C m., op. 60. Three trios for pf, vl, vc, E, op. 8; C, op. 87; C m., op. 101. Trio for pf, vl, horn, Eb, op. 40. Trio for pf, clar, vc, A m., op. 114. Quintet for clar, 2 vls, vla, vc, D m., op. 115. Three sonatas for pf and vl, G, op. 78; A, op. 100; D m., op. 108. Two sonatas for pf and vc,

E m., op. 38; F, op. 99. Two sonatas for pf. and clar, F m., and Eb, op. 120.

C. Piano Works. For piano solo Brahms wrote three sonatas in C, op. 1; F♯ m., op. 2; F m., op. 5. Schumann called them "symphonies in disguise." These, together with the great Scherzo in Eb m., op. 4, constitute the works of the composer's storm-and-stress period. In spite of their strong individuality and extraordinary beauty we feel the youthful exuberance of a Titan has done some violence to the symmetry of the form and in its almost overwhelming power forced the instrument beyond its natural limits. Brahms himself seems to have felt this, for, with the exception of the Ballads, op. 10, he wrote for the piano for many years nothing but variations—a form admirably suited to the cultivation of artistic restraint. These sets of variations consist of 16 var. on a theme of Schumann, op. 9, 11 var. on an original theme, op. 21, No. 1; 13 var. on a Hungarian song, op. 21, No. 2; 25 var. and fugue on a theme of Handel, op. 24; 28 var. on a theme of Paganini, op. 35. From 1860 to 1879 not a single composition for piano appeared. When at last the master wrote again for this instrument, he limited himself to small forms, which he filled with exquisite poetic content. These works comprise the opus numbers 76, 116, 117, 118, 119. Only in op. 79, containing those two magnificent Rhapsodies in C minor and G minor, does he attempt a larger form. For piano four hands Brahms wrote 10 variations on a theme by Schumann, op. 23, and a set of 16 charming waltzes, op. 39. The popular Hungarian Dances, arranged from themes of national composers, appeared without opus numbers.

As a composer for the piano Brahms must yield the palm to Chopin, and perhaps also to Schumann. It is, however, the only field in which he has been surpassed by any one.

D. Organ Works. For this instrument the master has written a Fugue in A♭ minor, a *Choralvorspiel* and *Päuge*, and a set of 11 *Choralvorspiele*, his very last work, all without opus numbers. Only in two other works does the organ figure as the accompanying instrument, the 13th Psalm for female voices, op. 27, and *Geistliches Lied* for mixed chorus, op. 30.

E. Vocal Works. (a) *With Orchestra.*—The greatest of these, the German Requiem, op. 45, has been mentioned. *Ave Maria*, op. 12, for female voices, was published in 1861. In 1869 appeared the cantata *Rinaldo*, op. 50, in which certain themes are employed as typical phrases after Wagner's manner in the *Flying Dutchman*. The following year brought forth a Rhapsody based on Goethe's *Harzreise im Winter*, op. 53, a work of lofty simplicity. In the *Schicksalslied*, op. 54 (1871), the composer contrasts, in accents of overwhelming grandeur, inexorable, pitiless fate and suffering, helpless humanity. Brahms's patriotism and interest in the political events of the time found a fitting expression in the *Triumphlied*, op. 55 (1872), dedicated to Emperor William I in commemoration of the victory won by the German arms. In 1881 the death of Anselm Feuerbach (q.v.) inspired the composition of *Némie*, op. 82, one of the noblest dirges in all music. The last of these great choral works, *Gesang der Parzen*, op. 89 (1883), is a work of almost depressing gloom and awful solemnity.

(b) *With Accompaniment of Other Instru-*

ments—*Begrabnisgesang*, op 13 (1861), with wood and brass instruments, female choruses, op 17 (1862), with two horns and harp, two songs for contralto, with piano and viola, op 91

(c) *A cappella*—For mixed chorus *Marienlieder*, op 22, 2 *Motetten*, op 29, 3 *Gesänge*, op 42, 7 *Lieder*, op 62, 2 *Motetten*, op 74, 5 *Gesänge*, op 104, *Fest und Gedenksprüche*, op 109, 3 *Motetten*, op 110 For female chorus 3 *geistliche Chöre*, op 27, 12 *Lieder und Romanzen*, op 44, 13 *Kanons*, op 113 For male chorus 5 *Lieder*, op 41

(d) *Songs*—Throughout his career Brahms cultivated the song, and it is perhaps as a song writer that the master is best understood and loved by the general public. In spontaneity of melodic invention, delineation of mood, and range of emotional expression he rivals Schubert, while in the matter of correct declamation and expressive elaboration of the piano accompaniment he surpasses the older master. The total number of Brahms's songs is 194, published in 31 opus numbers. Besides these original songs he arranged 14 *Volks Kinderlieder* and 7 books of genuine folk songs. On the same high level as the songs for one voice are the vocal duets and quartets. Among these latter the *Liebeslieder*, op 52, and *Neue Liebeslieder*, op 65, are especially remarkable for their striking originality of form. In reality they are instrumental waltzes for four hands with vocal quartet *ad libitum*, both parts being written with such independence that either can be performed without the other.

Brahms's position in the history of music may even now be regarded as definitely settled. With his great choral works he stands by the side of Bach, as an instrumental composer he ranks with Beethoven. His style is the ideal combination of the order polyphonic and the later homophonic art. All his works are stamped with the characteristics of a distinct, powerful individuality. Severity and sublimity are the predominant traits of his music, but the gentler emotions and genuine humor are by no means lacking. More than any other of the great masters Brahms has sought inspiration at the inexhaustible fount of folk music, and no one ever equaled him in the skill with which he molded this simple material into imperishable works of art. His melodic line is always broad and noble, his harmony, however bold, saturated with euphony, his rhythm incisive and infinitely varied. Hand in hand with these qualities goes a sovereign mastery of technique. Brahms not only has shown that the possibilities of the instrumental forms had not been exhausted by Beethoven, but he has conclusively proved that those forms are practically inexhaustible in the hands of a supreme master. With Brahms, as with Beethoven, the form is eminently plastic, it always adapts itself to the content. Brahms, just as Beethoven had done before him, has re-adjusted or extended details with utmost freedom, according to the exigencies of the thematic material. The occasional introduction of a third subject in extended movements, the employment of contrasting slow and fast tempi within the same movement, the introduction into a symphonic movement of contrapuntal complexities formerly considered practicable and permissible only in the fugue, affect only the detail of arrangement and disposition within the form, they do not touch the fundamental laws under-

lying the architectonic structure. Such infinite variety and elasticity prove the inherent vitality of the form.

Just as Beethoven had begun at the point where Haydn and Mozart had left off, so Brahms began by continuing the achievements of Beethoven's third period. But as these mark the highest conceivable development of absolute music Brahms could not rise higher. As a matter of fact no development is traceable in the master's works after the extremely brief period of storm and stress is passed. What constitutes the peculiar greatness of Brahms is his own powerful individuality, the deep earnestness and absolute sincerity of his music, the scrupulous avoidance of everything that is commonplace.

Thematic catalogue by N. Simrock (Berlin, 1902).

BRAHUI, bra-hū'ē. The aboriginal population who preceded the Baluchis in Baluchistan, and are now the dominant people, chiefly in the region centring in Kelat, from Quetta on the north to Las Bela on the south. Both physically and linguistically they are said to be related to the Dravidian tribes of India. It is held by some that many of the so-called Brahui adopted that language in quite modern times, having given up their original tongue, said to have been Kurd-gal. The Brahui profess the Sunnite creed of Islam with native additions and modifications. Physically they are well built, thickset, short in stature as compared with the tall Baluchis, and have round faces, with brown hair and beards. Some of these traits may be due to their mountain environment. Consult Trumpp, "Grammatische Untersuchungen über die Sprache der Brahuis," in *Sitzungsberichte der königlichen bayerischen Akademie der Wissenschaften, Philosophisch-philologische Klasse* (1880), Bellew, *Indus to Euphrates* (London, 1874), Hughes-Buller, *Report on the Census of Baluchistan* (1902), Biggswitter, *Guide to the Study of Brahui* (Allahabad, 1909).

BRAID, JAMES (c1795-1860). An English physician and writer on hypnotism, born in Fife, Scotland. He studied medicine in Edinburgh and settled as a surgeon in Manchester. He is especially noted for his researches on the subject of animal magnetism, for which he originally used the term *neurohypnotism*, later shortened into the term *hypnotism*. He read a paper at the meeting of the British Association in Man-

chester on June 29, 1842, entitled *Practical Essay on the Curative Agency of Neurohypnotism*, and in 1843 he published his work *Neurohypnotology, or The Rationale of Nervous Sleep Considered in Relation to Animal Magnetism*. See HYPNOTISM.

BRAIDISM. See HYPNOTISM.

BRAIDWOOD, THOMAS (1715-1806). An early and successful Scottish teacher of deaf-mutes. After graduating from Edinburgh University, he became a school teacher. He was for a short time assistant in the grammar school at Hamilton, and later opened a private school in Edinburgh. This was the first school for deaf-mutes in the British Empire. In 1760 a boy born deaf was placed with him to be taught writing. Braidwood taught him to speak and accepted other deaf students. In 1783 the school was given a royal grant of £100 a year and moved to Hackney, near London. His method was not allowed to be known outside his own family for many years, consequently his family enjoyed a monopoly, teaching it after his death. He used the Hemicke system principally, "reading from the lip," giving prominence to attempts at articulation. A little work, called *Vox Oculis Subjecta*, published by an American, Green, whose son was educated there, gives a good idea of the school in Edinburgh.

BRAIL (OF. *braiel*, a breech girdle, cincture, from Lat. *bracc*, breeches). A rope fitted to a fore-and-aft sail for the purpose of hauling it in to the mast when taking it in (the reverse of setting or spreading it). Brails are usually fitted in pairs and lead from the after boltrope of the sail to small blocks or dead-eyes on the mast and thence down to the deck. To "brail up" is to haul the sail close in to the mast ready for furling.

BRAÎLA, bră-î-lă, BRAILOV, bră-î-lôf, or IBRAIL, îb-ră-êl'. A town of Rumania, in Wallachia, situated on the left bank of the Danube, about 102 miles northeast of Bucharest (Map: Turkey in Europe, G 2). It is a place of great commercial importance, being the centre of the grain export trade of Wallachia. Among its industries are cement, corn and flour, and rolling mills; also manufactories of soap, candles, rope, and twine. In the vicinity are mud baths and sulphur springs, the strongest of their kind, and among the best known in Europe. After 1774 it was converted into a strong fortress by the Turks, but was unable to withstand the Russians in 1828. It has ceased to be a fortress, Galatz having supplanted it. Pop., 1905, 58,965; 1909, 60,259; including a number of Greeks and Bulgarians.

BRAILLE, bră-y', LOUIS (1809-52). A French teacher of the blind, who himself was blind from his third year. He was born at Coupvray and in 1810 went as a founding to the Institute for the Blind in Paris. There he became a teacher in 1828 and in 1829 devised his point system of writing for the blind. See BLIND, EDUCATION OF THE.

BRAIN. See NERVOUS SYSTEM.

BRAIN, DISEASES OF THE. These consist of disturbances of the circulation; inflammations following infections, injury, etc.; hemorrhages, degeneration, sclerosis, softening, malformations, and disorders called functional because no anatomical lesion is found after death that is regarded as due to the disorder or causative of it. A few of the common diseases of the brain will be considered. *Anæmia* and *hyperæmia* of

the brain are conditions, rather than diseases, and are considered here for convenience' sake. In the latter there is an excessive amount of blood in the cranial cavity, in the former there is too small an amount of blood in the vessels of the brain. *Anæmia* may be due to arterial disease, kidney disease, syphilis, wasting diseases, hemorrhages, faulty digestion, or fright. Its symptoms are faintness, vertigo, confusion of mind, and nausea. *Hyperæmia* is caused by the use of alcoholic beverages, by injury, sunstroke, prolonged mental overwork or worry, or by obstruction to the return of blood from the brain. The symptoms are headache, vertigo, insomnia, ringing in the ears, confusion of ideas or inability for mental application. Abscess of the brain is an acute suppurative inflammation of a limited area of the brain substance, with a production of pus. It is caused by infection by pus germs from middle ear or mastoid disease, or from the nasal cavities, by injuries, tumors, or by infectious diseases, such as diphtheria, typhoid fever, smallpox, *la grippe*, etc. Paralysis generally occurs, with headache, vomiting, and delirium. Trephining is the only treatment. "Softening of the brain" is the common (erroneous) term for any form of mental disease in which there is failure of mental power; and especially for general paresis, in which in reality a hardening occurs. True softening follows embolism (q.v.) or thrombosis (q.v.), in which the blood supply is cut off from a part of the brain, which generally becomes red or yellow, dies and softens, and may be absorbed or may go on to the production of abscess. Softening causes marked mental changes resembling those of dementia and sometimes paralysis. Brain palsies of children are either paralysis of one side of the body, or of both sides of the body, or of both lower extremities. The lesions are in the upper motor segments of the hemispheres of the brain and are due to injuries or disease of the mother during pregnancy or injury of the child during birth. Wasting of the paralyzed limbs occurs as the children grow, with the production of contracted muscles, clenched hands, or club feet. *Brain fever* is a popular and erroneous term, which is generally applied to meningitis, though used for other affections and conditions. *Inflammation of the brain* is also an erroneous term, signifying usually meningitis or abscess of the brain. Encephalitis without meningitis or abscess is a rare condition, but according to Gowers and other authorities may occur, although difficult of diagnosis. *Tumors* may be either tubercle, syphiloma, glioma, or sarcoma, or other less common forms, as all varieties of new growths may be found in the brain. They are all rare. They generally cause intense and constant headache, vomiting, with or without nausea, vertigo, changes in sensation, convulsive movements of upper or lower extremity or of the face without loss of consciousness, deterioration of sight and some mental defect. Treatment depends upon the variety of tumor and its location. Tubercular or syphilitic tumors are the most favorable, as regards possibility for treatment. See APOPLEXY; APHASIA; CONCUSSION OF THE BRAIN; EMBOLISM; THROMBOSIS; EPILEPSY; PARALYSIS; SCLEROSIS; STYPHILIS.

BRAINARD, DAVID LEOGE (1856-). An American explorer, born in Norway, Herkimer Co., N. Y., and educated in the common schools and the State Normal School at Cortland. He

enlisted as a private in the United States army in 1876 and served in Indian campaigns under Gen Nelson A Miles. In 1881 he was first sergeant of the Lady Franklin Bay expedition under Lieut (now Gen) A W Geely, and was a member of the party of three who (on May 15, 1882) reached lat 83° 24' 30". This remained the highest latitude reached by explorers for 13 years, and the most northern known point of land for 18 years. Upon his return he became a sergeant in the Signal Service and afterward was commissioned a second lieutenant in the Second United States Cavalry. He served in the Alaskan government relief expedition in 1897, was made a colonel in the subsistence department of the United States in 1898, and went to the Philippines in 1900 as major, in that department, in the regular army. In 1905 he became lieutenant colonel and deputy commissary general of the United States army. Consult Humphreys, *Missionary Beploires among the American Indians* (New York, 1913).

BRAINARD, JOHN GARDINER CALKINS (1796-1828). An American poet and editor, born in New London, Conn., Oct. 21, 1796. He was graduated at Yale in 1815, studied law, practiced at Middletown, Conn., but in 1822 went to Hartford to edit the *Connecticut Mirror*, which he brought into general notice by his literary contributions, especially ballads. After five years failing health obliged him to give up his editorship, and after brief retirement in Long Island he returned to New London to die, continuing poetic composition to the last. He had collected his poems in 1825. A full edition, *Literary Remains*, with a biographical sketch, was made by John G. Whittier, his successor as editor of the *Mirror*, in 1832. It passed through three editions in 10 years, but his facile verse is now almost forgotten. Brainard died in New London, Sept. 26, 1828.

BRAINE-LE-COMTE, brân'le-kôm'té (anciently, Lat *Brenna Comitis*). A town in the province of Hainaut, Belgium, 19 miles southwest of Brussels (Map Belgium, C 4). It formerly belonged to the monks of St Waudru at Mons, from whom it was bought by Count Baldwin in 1158. It has an old church of the thirteenth century, cotton and corn mills, dye works, breweries, paper factories, and stone quarries. A very fine quality of flax is grown in the district. Pop., 1900, 8935, 1910, 9438.

BRAINERD, brân'erd. A city and the county seat of Crow Wing Co., Minn., 139 miles north by west of St Paul, on the east bank of the Mississippi River, and on the Northern Pacific and the Minnesota and International railroads (Map Minnesota, C 4). The Northern Pacific has here large machine, car, and other shops, and a hospital. The city also contains St Joseph's Hospital, a fine courthouse, Y M C A building, a Carnegie library, a public park, and athletic grounds. A dam across the Mississippi furnishes water power for various manufactures. There are extensive lumber yards, cigar factories, large foundry and machine shops, flour mills, paper and pulp mill, etc. The Cuyuna iron range extends northeast and southwest through Brainerd. The city is important as the commercial centre for the adjacent region, the export trade consisting largely of lumber, grain, hay, furs, and iron. Brainerd was chartered as a city in 1883. The water works and electric light plant are operated by the city. Pop., 1890, 5703, 1900, 7524, 1910, 8526.

BRAINERD, DAVID (1718-47). An American missionary born in Haddam, Conn. His missionary work was among the Indians in Massachusetts and those around the Delaware and Susquehanna rivers. He died at Northampton, Mass., at the house of Jonathan Edwards, who wrote his biography (Boston, 1749). As missionary classics (best ed J M Sherwood, New York, 1884), that and Dained's *Journals* are well known. His brother, JOHN BRAINERD (1720-51), continued his labors among the Indians.

BRAIN FEVER. See BRAIN, DISEASES OF.

BRAIN STONE. See CORAL.

BRAINTREE. A town, including the villages of South and East Braintree, in Norfolk Co., Mass., 10 miles south of Boston, on the New York, New Haven, and Hartford Railroad. It has granite quarries, metal foundries, and manufactures of boots, shoes, leather, tacks, naturalized rubber, rubber cement, conductors' punches, etc (Map Massachusetts, E 3). The town contains Thayer Academy and the Thayer Public Library. The government is administered by town meetings. The water works and electric light plant are owned by the municipality. First permanently settled in 1634, when the General Court of Massachusetts ordered that Boston, being "too small to contain many," "shall have convenient enlargement at Mount Wollaston." Braintree was incorporated as a town in 1640. In the portion of old Braintree now included within the limits of Quincy, Thomas Morton (qv) established his "New Canaan" at "Merry-mount" (Mount Wollaston), and John Adams, John Hancock, and John Quincy Adams were born. The township included Quincy (qv) until 1792 and Randolph until 1793. Pop., 1900, 5981, 1910, 8526. Consult Pattee, *History of Old Braintree and Quincy* (Quincy, 1878); Adams, *Three episodes of Massachusetts History* (Boston, 1892); Bates (ed.), *Records of the Town of Braintree from 1610 to 1793* (Randolph, Mass., 1886); Wilson, Quincy, *Old Braintree, and Merry-mount* (Boston, 1906).

BRAITH, brith, ANTON (1836-1905). A German animal painter. He was born in Biberach (Württemberg) and studied first with Johann Baptist Plüg in his native city and later in the Art School at Stuttgart. In 1860 he removed to Munich and came under the influence of Piloty. There he gained renown as an animal painter, although he never satisfactorily solved the problem of color. Among his works are "The Herd before a Storm" (1867, Gallery of Cologne), "Return of a Flock of Sheep from the Alps" (1880, Stuttgart), "A Bright Morning" (1886, Berlin National Gallery), "The Peasant Woman's Pet" (1891, Munich), and "Cows at the Brook" (1896, the museum of his native town, which also possesses the best collection of his drawings).

BRAIZE (probably akin to *bream*, OF *bresme*, cf OHG *brāhsima*, *brāhsa*, *brēam*), or BECKER. 1. A British sparoid marine food fish (*Sparus pagrus*), commonly called porgy, seup, or king of the breams (See BREAM). 2. In Scotland, the roach.

BRAKE (OE *brake*, LG *brake*, Ger *Brache*, a tool for breaking flax, from the same root as *break*). A mechanical contrivance consisting usually of a shoe or band applied to the surface of a rotating shaft or wheel in such a manner that motion is retarded by means of the friction. A shoe brake consists of a wood or metal block or shoe which is pressed against the rim of a wheel by means of a system of levers. The

BRAKE AND BIRCH

1. BRAKE (*Pteris aquilina*).

2. COMMON WHITE BIRCH (*Betula alba*), in early May
near New York City.

hand brakes used on railway cars and the foot or hand brake used on horse-drawn vehicles are familiar examples of shoe brakes. Band brakes consist of a flexible band looped around the perimeter of the wheel and contrived so that it may be tightened and thus grip the wheel. Such brakes are extensively used on hoisting engines and motor vehicles, and also on some makes of bicycles. The internal expanding shoe brake, where by means of a toggle linkage or cam a hinged shoe is forced against the interior of a drum by simple lever action, is found on many motor cars. Perhaps the most elaborate braking mechanism in common use is the air brake for railway cars. (See AIR BRAKE.) The Prony brake is a form of band brake used to measure the horse power of a rotating shaft or pulley, and is more properly classed as a dynamometer than as a brake.

BRAKE (AS. *bracce*, a fern). A popular name for the cosmopolitan ferns of the genus *Pteris*. This genus is a member of the family Polypodiaceæ and is distinguished by having the spore cases situated along the edges of the leaves and covered by the reflexed margin of the frond. The common brake or bracken (*Pteris aquilina*) is very abundant in most parts of the world, growing in heaths, parks, etc., often covering considerable tracts. It has a long, creeping, black rhizome, or rootstock, from which grow up naked stalks of 8 to 18 inches or more in height; each stalk divides at the top into three branches; the branches are bipinnate, the inferior pinnales pinnatifid. The rootstock, when cut across, exhibits an appearance which has been supposed to resemble a spread eagle, whence the specific name *aquilina* (Lat. *aquila*, an eagle). The rootstock is bitter and has been used as a substitute for hops; it has also been ground, mixed with barley, and made into a wretched bread in times of distress. The plant is astringent and antelmintic, and as such it had at one time a high reputation, although it is now little used, at least by medical practitioners. It is employed in dressing kid and chamois leather. Brake is also employed for thatching, for littering cattle, etc., and is occasionally chopped up with straw or hay for feeding cattle. It is a favorite cover of deer and other game. The abundance of this plant is sometimes regarded as a sign of poor land, although, probably, its absence from the richer soils is very much a result of cultivation. To extirpate it, nothing more is necessary than a few successive movings of the young shoots as they appear. The annual growth of brake is killed by first frosts of autumn, but remains rigid and brown, still affording shelter for game, and is almost as characteristic a feature in the landscape of winter as in that of summer, perhaps adding to its general desolateness. *Pteris caudata*, a large species of brake, very similar to that of Europe, is one of the worst pests which the farmer has to contend with in the south of Brazil. *Pteris esculenta*, a native of New Zealand, Van Diemen's Land, etc., has a rhizome more nutritious than that of the common brake. Two species, *Pteris orelica* and *P. serrulata*, are common household plants.

BRAKELONDE, bråk'lönd, JOCELIN DE. See JOCELIN DE BRAKELONDE.

BRAKSY. See BRAXY.

BRAMA (probably akin to *bream*; see BRAZYE). A genus of fishes of the family Chætodontidæ. *Brama raiti* is common in the Medi-

terranean and occasionally found on the British shores, where it is called sea bream and gilt-head. The genus has the body very deep and compressed, the head rather obtusely terminated, a single elongated dorsal fin, and the anal fin with a very lengthened base. The tail is forked, its points extremely divergent. This fish is sometimes more than two feet in length. Its flesh is of exquisite flavor. See SEA BREAM.

BRAMAH, brä'mä, JOSEPH (1748-1814). A practical machinist, born at Stanborough, Yorkshire, England. Unable to work on his father's farm on account of lameness, he was apprenticed to a carpenter and joiner and afterward obtained employment with a cabinetmaker in London, where subsequently he established himself in business and became distinguished for the number, value, and ingenuity of his mechanical inventions, such as safety locks and improvements in pumps and fire engines, in the construction of boilers for steam engines, in the processes of making paper, in the construction of main pipes, wheel carriages, printing machines, and the beer machine used at the bar of public houses. In 1795 he patented his most important contribution to mechanics, the hydraulic press known by his name.

BRAMAH'S PRESS. See HYDRAULIC PRESS.

BRAMANTE, brä-män'tä, DONATO D' AGNOLO, often called LAZZARI (1444-1514). One of the principal architects of the Italian Renaissance. He was probably born at Monte Asdrualdo, near Urbino; practiced painting under Piero della Francesca and Mantegna and executed works in Milan and Bergamo (1472-77), but soon devoted himself entirely to architecture. His career falls into two main divisions: (1) The 28 years of early work in Milan, 1472-99; and (2) the 15 years of work in Rome, 1499-1514. Each period is marked by a style so distinct that some have questioned whether their works were really by the same master. The most important of his Milanese works are the transept, apse, and sacristy of San Satiro (c.1480-88); his masterpiece in decoration and composition, the choir and dome of Santa Maria delle Grazie, with its perfect union of brickwork with details in terra cotta and marble; and parts of the Ospedale Maggiore. In the choir of Santa Maria delle Grazie he was the first to apply candelabrum shafts as an exterior decoration to pilasters, a device widely imitated in France and Spain after the battle of Pavia (1525). Outside of Milan are the simple but masterly composition of a façade at Abbiategrasso and the octagonal Canopanovo Church in Pavia. To him have been ascribed the cathedral of Pavia, the nave of Como Cathedral, the Inconronata at Lodi, the Consolazione at Todi, and many other works with which his connection is problematic or wholly fictitious; but these ascriptions prove the extent of his influence in Lombardy and its long duration after his departure from Milan and even after his death.

At the age of 55 Bramante went to Rome. Hitherto he had seen the antique through the interpretations of his Renaissance predecessors, from Brunelleschi (q.v.) to Fra Giocondo (q.v.), through such masters as Alberti (q.v.) and Laurana (q.v.). He now went for the first time to the fountain head. The transformation of his style which followed was due not only to the overpowering effect of the Roman monuments, but also to the necessities of the change in the materials with which he had to work. In Lom-

bardy brick predominated, and his Lombard style was formed by work in brick and terra cotta, in Rome he was to work in masonry of cut stone, at least in all his major works. Considering his age, the rapidity of his adjustment of style and conception to the new conditions is astonishing evidence of his genius. His new manner inaugurated the period of the Middle Renaissance, of which he became the leader. The patronage of the Popes gave him the opportunity Alexander VI and Julius II employed him on important buildings. Bramante brought to Rome his love of dome construction, and a thorough knowledge of perspective and of the engineering and constructive side of his art. To this equipment he joined a remarkable appreciation of the essential qualities of antique Roman architecture—its scale, its monumental stateliness, its breadth of design. He expressed himself almost immediately in an exquisite gem, the circular tempietto at San Pietro in Montorio, famous "as the first building after a lapse of 1200 years built entirely in the ancient spirit and style." Soon after came the cloister of Santa Maria della Pace, also a classic. Both buildings gave the tone for the pure, cold style of the sixteenth century. Bramante's part in the design of the grand Cancelleria Palace, and the smaller Gnaudi-Torlonia Palace, is a subject of much controversy. The first was begun before he came to Rome, the second after his arrival. There are elements in both which link them on the one hand to Lombard types, on the other to his work on the Vatican, and there is little doubt that he at least completed both. Many authorities, however, ascribe their original design to some unknown architect from the north.

Bramante was in 1503 intrusted with the planning of the greatest architectural labor of the Renaissance, the reconstruction of the Vatican Palace and of St. Peter's. His plans for St. Peter's, though only partly carried out, were known through drawings to all architects and exercised an enormous influence. They comprised a huge dome over the intersection of the arms of a Greek cross with apsidal terminations, and with towers, chapels, and loggias filling the four angles. He designed the two immense wings or galleries of the Vatican, to connect the older palace with a group nearly 1500 feet away to the north, but himself erected only the east gallery, with the northern block comprising the impressive *Nicchione*, or apse, and the Cortile di San Damaso at the southern end, this was later decorated by Raphael (see LOGGIE, RAPHAEL) and his pupils. His death in 1514 put both these undertakings into other hands. But during his last years he had developed his latest manner, as is shown in his own palace in Rome ("Raphael's house"), and in the Palazzo di San Diego, where the rustic work on the lower story and the engaged columns above, no longer existing, furnished a type that was used by Raphael, Sanmichele, Sansovino, Palladio, and other leading architects. Consult Von Geymuller, *Die ursprünglichen Entwürfe für die Peterskirche* (Vienna, 1875), Semper, in Dohme, *Kunst und Künstler* (Leipzig, 1879), and Vogel, *Bramante und Raphael* (Leipzig, 1910).

BRAMBACH, bram'bag, KASPAR JOSEPH (1833-1902). A German composer. He was born in Bonn and was a pupil of Ferdinand Hiller. He was first violinist of the opera orchestra in Bonn from 1847 to 1850, and musical director in that city from 1861 to 1869. His works in-

clude an opera, *Antadne*, and the well-known cantatas, *Das eleusische Fest* (op. 32), *Trost in Thänen* (op. 10), *Die Macht des Gesanges* (op. 6), *Columbus* (op. 58, 1886), *Frühlingssymnus* (op. 37), *Alceste* (op. 14), and *Prometheus* (op. 47), all of which enjoy considerable popularity and are frequently performed.

BRAMBLE (akin to Ger *Bram*, *Brame*, the broom tree). A name used in America as a collective term for all plants of the genus *Rubus*, including the raspberry, blackberry, and dewberry. In Great Britain it is used to distinguish the native blackberry (*Rubus fruticosus*), which bears an inferior fruit, from the raspberry and others of that type. The bramble is a common wild plant in Great Britain and most parts of Europe. Although it is abundant everywhere and bears fruit of fair quality, it has never attracted much attention from cultivators because of its weedy nature. In fact, it was considered a nuisance and was so referred to in literature as far back as Shakespeare's time. See BLACKBERRY, RUBUS.

BRAMBLING (from *bramble*, Ger *Bramling*), or MOUNTAIN FINCH. A large, brightly colored finch (*Fringilla montifringilla*), nearly allied to the chaffinch, which during migrations appears in large numbers throughout Europe and parts of Asia, to the northern borders of which it resorts to breed in the birch forests.

BRAMPTON. The capital of Peel Co., Ontario, Canada, and a busy junction of the Canadian Pacific and Grand Trunk railroads, 21 miles northwest of Toronto (Map Ontario, E 6). It manufactures flour, boots and shoes, office supplies, paper boxes, elevators, and bricks; has a considerable trade in cut flowers, cattle, and hogs, and is a market for grain and produce. Pop., 1901, 2748, 1911, 3412.

BRAMWELL, SIR FREDERICK (1818-1903). An English civil engineer, born in London. In 1856 he became an associate of the Institution of Civil Engineers and in 1884 its president. In 1888 he was elected president of the British Association. He was prominent in many important undertakings in connection with his profession and was also long active in endeavoring to promote the technical education of workmen.

BRAMWELL, JOHN MILNE (1852-) An English physician and author. He was born at Perth, N. B., and was educated at the University of Edinburgh. He devoted considerable study to hypnotism and combined the French methods of hypnosis respectively employed in Paris and Nancy with good results. He wrote *Successful Treatment of Dipomania, Insomnia, etc.*, and *Various Diseases by Hypnotic Suggestion* (1890-92), *Hypnotic Anaesthesia* (1896), *On the Appreciation of Time by Somnambulists* (1896), *Suggestion Its Place in Medicine and Scientific Research* (1897), *Hypnotism Its History, Practice, and Theory* (1903), *Hypnotism and Treatment by Suggestion* (1910).

BRAN (OF *brén*, *bran*, *brian*, Welsh, Ir *bran*, husk, chaff). The outer coat of wheat, rye, and other cereal grains, separated from the flour in milling by bolting. Wheat bran is often spoken of simply as bran, while rye bran, corn bran, rice bran, etc., are usually referred to under their full names. Wheat bran is extensively used and highly prized as a feeding stuff for nearly all kinds of farm animals. Fed with corn meal (maize), the combination is hardly surpassed for cows, the bran furnishing not

only the bulk, but the protein and ash which are necessary to milk production. The other kinds of bran are much less abundant in quantity, but are utilized quite generally for feeding purposes. The average percentage composition of different kinds of bran, from a large number of American analyses, is shown by the following table:

KIND OF BRAN	Protein	Nitrogen-free extract	Fat	Fibre	Ash	Water
Bran from spring and winter wheat.....	15.4	53.9	4.0	9.0	5.8	11.9
Rye bran	14.6	54.0	3.8	3.4	3.4	11.8
Rice bran	12.6	50.0	9.5	8.9	0.4	9.3
Corn bran	19.0	63.1	3.8	11.7	1.4	9.4
Buckwheat bran	12.6	37.9	3.5	32.9	4.9	9.2

Middlings, or shorts, contain some of the finer bran and coarse flour, although they are of the same origin as bran, viz., from the outer coat of the grain. They contain less fibre and ash—mineral matter—than bran and are considered better suited to pigs and horses.

The black woody hulls of the buckwheat grain have little feeding value; but the portion lying immediately under the hulls, which forms the middlings, is rich in protein and fat and has a high feeding value. The hulls and middlings are often mixed and sold as buckwheat bran, in which case the proportion in which they are mixed determines the value of the bran.

Wheat bran contains in 1000 pounds about 265 pounds of nitrogen, 290 pounds of phosphoric acid, and 160 pounds of potash. The same amount of rye bran contains 230 pounds of nitrogen, 230 pounds of phosphoric acid, and 140 pounds of potash. Hence, in feeding these materials, the fertility of the farm is being added to if the manure is properly cared for and used. Bran is used in dyeing and in calico printing.

BRAN. The dog of Fingal. There was a Scottish tradition, before Macpherson's *Ossian* appeared, that a southern chief challenged Fingal to hunt Bran in Sledale against his own dog, Phorp, of the same breed, the present Scottish deerhound. The dogs ran equally well all day; so, as a further test, their owners set them fighting. Bran was getting the worst of it, when the chief said something about Bran which angered Fingal, who seized Phorp, and with his charmed hand tore his heart out. But Bran suffered so in the fight that he died in Glen Loch and was buried there.

BRAN, THE BLESSED. The name of the hero of the poem *Myssyrian*, by Tälisen. He was the knight who found a vessel of decoration and mystic connections similar to those of the Holy Grail.

BRANCA, brän'ká, ASCANTIO (1840-1903). An Italian statesman. He studied law at the University of Naples, became known as a journalist and economist, and in 1870 was elected to the Chamber of Deputies, where in 1885 he joined the party of the opposition. In 1891-92 he was Minister of Public Works, in 1896-98 of Finance, and again in 1900-01 of Public Works. He published *Lo crédit et la banque internationale* in 1871.

BRANCH. See BRANCHING.

BRANCH, JOHN (1782-1863). An American politician. He was born in North Carolina, and graduated at the State University in 1801. He was State Senator from 1811 to 1817, Governor of North Carolina from 1817 to 1820, and from 1823 to 1829 served in the United States Senate. He then was Secretary of the Navy under President Jackson from 1829 to 1831, a Democratic member of Congress from 1831 to 1833, and Governor of the Territory of Florida from 1844 to 1845.

BRANCHIA. See GILL.

BRANCHIATA, brän'ki-ä'tä (Neo-Lat. neut. pl. of *branchiatus*, having gills, from Lat. *branchia*, Gk. βράγχια, *branchia*, gills). One of the two great branches or subtypes into which the Arthropoda (q.v.) are divided, the other being the Tracheata. They are characterized by the presence of gills in some form, though it may be only as thin portions of the body integument. They have no tracheæ or tracheal tubes of any sort and breathe air only as it is present in water. Many of the very small forms, and some of the larger ones, apparently have no distinct gills, but receive the oxygen which they need through a part or all of the body surface. In accordance with their manner of breathing, the Branchiata live in water either fresh or salt, and the exceptions to this rule are to be found only among the higher groups, where certain species have special structural features that enable them to live a greater or less time on land, usually, however, in damp places. The classification of the Branchiata is perplexing; for while the one class Crustacea (q.v.) is well defined, there are a few other living, and many fossil forms like the king crabs and trilobites, which present the greatest difficulties.

BRANCHIDÆ, brän'ki-dë (Gk. βράχιδαί, *Branchidai*, also called *Didymoi*, Διδύμοι, *Didymoi*, or *Didyma*, Διδύμα). A place on the seacoast of Ionia, a little south of Miletus and near Panormus, celebrated for its temple and oracle of Apollo Didymeus. The hereditary ministers of this oracle, which was one of the most famous of the Greek world, were the Milesian Branchidæ, who traced their descent from Branchus, a favorite of Apollo. When the oracle was instituted is not known, but its first period of great celebrity was in the sixth century B.C. The temple and the oracle were destroyed, either (according to Herodotus) by Darius at the time of the destruction of Miletus, 494 B.C., or (according to Strabo, Plutarch, and Pausanias) by Xerxes some years later. Xerxes exiled the Branchidæ to the far northeastern part of the Persian domain. The temple was rebuilt, after 332 B.C., but on so grand a scale that it was never fully completed and always remained without a roof; its ruins contain some beautiful specimens of the Ionic order of architecture. The ruins were explored in 1764 by Sir Richard Chandler, and in 1812 by Sir William Gell. Charles Thomas Newton (q.v.) also visited the site. The French examined the ruins in 1873 and sent some sculptural fragments to the Louvre; they made a more detailed search in 1895, through M. E. Pontremoli and M. B. Hausoulle. Later, the French surrendered their rights in the site to Th. Wiegand, a German archaeologist, explorer of Miletus. In 1905 he began to clear the great temple completely. Consult: Gelzer, *De Branchididis* (Leipzig, 1869); O. Rayet, *L'architecture ionique en Ionie; Le temple d'Apollon Didyméen* (Paris, 1876); C. T.

Newton, *History of Discoveries at Halicarnassus, Cnidus, and Branchidae* (London, 1862-63), E. Pontieri and B. Haussoullier, *Didymes* (1904)

BRANCHING (Fr *branche*, branch, It, Sp *branca*, branch, claw, from LL *branca*, claw, possibly from Lat *bra*[*cl*]eum, aim, claw.) There are two general types of branching, known as the "dichotomous" and the "monopodial." In the former the apex of the axis forks, the old axis ending at the point of branching. In some cases three branches may arise in this way, resulting in "trichotomy," or even more than three branches may arise by the division of a growing tip, but the term "dichotomy" is a general one, covering all cases of branches arising in this way, without reference to the number. Thallus bodies are particularly inclined to dichotomous branching, and hence its chief display is among the algae and fungi, the liverworts, and the prothallia of ferns. Among seed plants there are cases which resemble dichotomy, as in the branching of the lilac, but this is "false dichotomy," because, although two branches seem to arise from the apex of an axis in forking fashion, they are really lateral branches, the apex of the old axis remaining between them undivided but arrested in growth.

BRANCHING a, dichotomous, b, monopodial, c, sympodial

In monopodial branching the branches arise laterally from the axis. This type is characteristic of the seed plants, but it is found in the lower groups as well. In this case the tip of the main axis may continue to grow vigorously, and a central shaft may develop, as in the pines and firs, such a habit is called "excurrent," the main shaft "running through" the whole branch system. In other cases, as in the elm, some of the lateral branches are more vigorous than the main axis, which is presently lost sight of, and the trunk seems to be replaced above by a set of large divergent limbs, a habit called "deliquescent," meaning that the main axis is "dissolved" into branches. Sometimes what appears to be the main axis is really a series of strong lateral branches which simulate it. A strong lateral branch appears just behind the tip of the axis, pushes it aside in its growth, and continues the direction of the main axis, then a lateral branch from this first branch does the same thing, and so on until the principal axis consists of a series of strong lateral branches, as in the linden. Such an axis is called a "sympodium," and this sympodial development is apt to be characteristic of groups of plants.

The branching of roots is never so symmetrical as that of stems, the branches arising from any point, while those of the stems are related very definitely to the nodes, at which the leaves appear. Another characteristic of root branching is that the branches arise from the central woody cylinder and burrow their way through the cortex, while in stems the branches arise superficially, of course involving also the deeper tissues. The root type of branch origin is said to be "exogenous" ("inside origin"), and the stem type is "exogenous" ("outside origin"). This is the proper application of the terms "endogenous" and "exogenous," which were formerly misapplied to the stems of monocotyledons and dicotyledons respectively.

Leaves also frequently branch, and when the branches are quite distinct the leaves are said to be compound. This branching is determined by the venation, which is the system of vein branching. Accordingly, branching leaves may be either palmately or pinnately compound. See LEAF.

BRANCHIOPODA, brān'ki-ōp'ō-da (Gk gill-footed, from βράγχια, *branchia*, gills + πούς, *pous*, foot), or EUPHYLLOPODA. A suborder of Entomostriaca, with numerous *branchia*, or gills, attached to the feet, water fleas. The term has been used by different authors in a most confusing manner, but the latest writers regard the group as a division of Phyllopoa. Used in this sense the Branchiopoda may be defined as phyllopods with numerous distinct trunk segments and numerous pairs of swimming feet. There are three families containing about a half-dozen genera. The families are distinguished by the carapace which is wanting in one, shield-shaped in the second, and bivalve in the third. These animals are popularly known as "fairy shrimps."

BRANCHIOSAURUS, brān'ki-ō-sa'rūs. See STEGOCEPHALIA.

BRANCHUS. See BRANCHIIDE.

BRANCO, brān'kō (Port white, Sp *blanco*, It *bianco*, Eng blank), Rio. The principal tributary of the Rio Negro, Brazil (Map, Brazil, E 3). It rises near the frontier of Venezuela in the Parima Mountains, flows southwest, is 375 miles long, and is navigable for most of its length by light-draught vessels.

BRAND, brānt, JAN HENDRIK (1823-88). A President of the Orange Free State, born in Cape Town and educated in England. In 1864 he was elected President of the Orange Free State and was successively reelected in 1869, 1874, 1879, and 1884. In 1876, at the request of Lord Carnarvon, he visited England for the purpose of taking part in a conference which had as its object the establishment of a confederation of South African states. He opposed the project, which consequently failed. On the occasion of the first conflict between the Transvaal and England he was successful in bringing about peace negotiations between Sir Evelyn Wood and the Boer representatives. Consult Charles de Coutouly, "Un homme d'état afrikanderiste Jan Hendrik Brand" in *Revue historique*, vol. LXVI (Paris, 1901).

BRANDE, WILLIAM THOMAS (1788-1866). An English chemist. He studied medicine, became a fellow of the Royal Society, and assistant to Sir Humphry Davy, whom he succeeded in the chair of chemistry at the Royal Institution in London, 1813. From 1816 to 1836 he and Faraday were joint editors of the *Quarterly Journal of Science and Art*. In 1853

he received the honorary degree of D.C.L. from Oxford. He was the author of several works. His manual of *Chemistry* (1819) was one of the best text-books of the time; but his reputation rests chiefly upon his *Dictionary of Science, Literature, and Art* (1842).

BRANDEGEE, FRANK BOSWORTH (1864-). An American legislator, born in New London, Conn. He graduated from Yale University in 1885, studied law, and was admitted to the bar. In 1888 he was elected to the Connecticut House of Representatives, and also in 1899, when he served as speaker. For 10 years he was corporation counsel for the city of New London. As delegate he attended four Republican National Conventions. He was elected to Congress in 1902 to fill an unexpired term, and was reelected in 1903 and 1905. On May 9 of the latter year he was chosen United States Senator to fill the unexpired term of O. H. Platt, deceased, and in 1909 was reelected for the term expiring 1915. As chairman of the Senate Committee on Inter-oceanic Canals, he warmly opposed the action of the Senate in 1912 in passing measures providing for the free passage of American ships through the Panama Canal.

BRANDEIS, brain'dis, FREDERICK (1835-99). An American organist and composer. He was born in Vienna, Austria, where he studied under Fischhof, Czerny, and Kufnatscha. In 1849 he traveled through the United States with the William Wallace Opera Company and settled in New York City in 1851. He was organist of the Roman Catholic churches of St. John the Evangelist (1865-70) and St. James (1871-86) in New York; of St. Peter and St. Paul's Church in Brooklyn (1886-98), and of the Forty-fourth Street Synagogue in New York (1898-98). His compositions include a prelude to Schiller's *Maria Stuart*; *The Sunken Cloister*, a ballad for chorus and orchestra; a suite for string orchestra; and many instrumental and vocal pieces.

BRANDEIS, LOUIS DEMBITZ (1856-). An American lawyer and publicist, born at Louisville, Ky. He was educated in Louisville, at Dresden, Germany, and, in law, at Harvard. Though successful in the practice of his profession, he became more widely known through his interest in economic, social, and political problems. He was one of the earliest advocates of the adoption of a radical policy of conservation by the government, supporting Gifford Pinchot (q.v.) in the latter's attack on R. A. Ballinger and acting as counsel for Luther R. Glavis in the Ballinger-Pinchot investigation. (See *ALASKA, History*; *Public Lands*, and *UNITED STATES, History*.) In 1910 he appeared for the shippers in the hearing held before the Interstate Commerce Commission, relative to an increase in the freight rates asked for by the railroads. He was also counsel (for the people) during the proceedings involving the constitutionality of the Oregon and Illinois ten-hour laws for women, and in the New York garment-workers' strike of 1910 he was chairman of the arbitration board. The various inquiries and investigations into the New York, New Haven & Hartford Railroad in 1912-13 brought from him a vigorous denunciation of the road's administration. He is author of many articles on public franchises, wage-earners' life insurance, and other economic subjects, and of contributions to legal reviews.

BRANDENBURG, brân'den-bôrk. A prov-

ince of central Prussia (Map: Prussia, E 2). Berlin, geographically within the province, forms a separate administration. The province corresponds in part to the former electorate of Brandenburg; its area is 15,383 square miles; pop. (Census of Dec. 1, 1910), 4,092,616. It is very flat, and in some parts marshy, with a slight elevation towards the southeastern end. Brandenburg is exceptionally well watered both by rivers and lakes and by canals. The chief rivers are the Oder, with its numerous tributaries, and the Elbe, with its navigable tributary, the Havel. Lakes are very numerous (between 600 and 700), and some of them are connected by canals with the larger rivers. The climate is cold and raw in winter and hot in summer. Brandenburg has a very sandy and sterile soil, and it is only by artificial means that it has been made productive. The area under tillage is very extensive; in 1912, 459,864 hectares were under rye, 88,653 wheat, 95,840 summer barley, 343,850 oats, 177,511 potatoes (largely for distilling), and 386,759 meadow. The approximate number of live stock in December, 1912, was: horses, 361,000; cattle, 891,000; sheep, 806,000; goats, 86,700; swine, 1,180,000. The chief mineral product is brown coal, of which Brandenburg yields about 8,000,000 tons annually, and the mining of which gives occupation to over 10,000 men.

The manufacturing industries are developed to a very high degree. Brandenburg contains extensive silk, woolen, linen, and cotton cloth and yarn mills, and numerous establishments for the dyeing, spinning, and printing of different textiles. There are also machine shops, cigar and cigarette factories, glass and chemical works. The production of spirits and beer is extensive, and the sugar mills produce large quantities of beet sugar. The manufacture of women's garments is a prominent branch of industry. Brandenburg is exceptionally well provided with transportation facilities. Besides its several navigable rivers and excellent canal system, it has about 3900 miles of roads; in 1911 there were 2520 miles of standard-gauge railway, of which 2147 miles were owned or operated by the state.

For administrative purposes, the province is divided into the two districts (*Regierungsbezirke*) of Potsdam and Frankfurt (Berlin being separate, as stated above). It sends 36 representatives to the Lower Chamber (*Abgeordnetenhaus*) of the Prussian Landtag, and 20 members to the Imperial Reichstag. The seat of the governor is at Potsdam, of the general commission at Frankfurt, and of the provincial Landtag at Berlin. (For further particulars as to local administration, see *PRUSSIA, Local Government*.)

The population of the province in 1871 was 2,036,888; in 1880, 2,200,825 (the increase being 11.9 per cent); in 1890, 2,541,783 (11.4); in 1900, 3,108,554 (20.1); in 1910, 4,092,616 (27.3). In 1910 Protestants numbered 3,676,693 (89.84 per cent); Roman Catholics, 300,320 (7.34); Jews, 61,343 (1.50). These figures do not include Berlin. The general tendency of the population to leave agriculture for manufacturing pursuits, so strongly marked in all the Prussian provinces, is especially pronounced in Brandenburg, where a large falling off in the agricultural population since 1882 is accompanied by a still larger increase in the manufacturing population.

The various nations of Teutonic origin which

inhabited Brandenburg at the beginning of the Christian Era were replaced during the age of migrations by a number of Slavic tribes, whom Charles the Great vainly attempted to subdue. Henry I succeeded in exacting tribute from them, and Otto I divided their country into two marks, but the Slavs (Wends, Lutits, etc.) were not fully overcome till the middle of the twelfth century, when Albert the Bear, who styled himself Margrave of Brandenburg, about 1140 established the supremacy of the Germans by peopling the region with colonists from Westphalia and the Netherlands. Under the successors of Albert the feudal authority of Brandenburg was extended over Pomerania, and territorial gains were made at the expense of Bohemia and Poland. Especially prosperous was the joint reign of the brothers John I and Otto III in the middle of the thirteenth century, in whose time the power of the nobles was greatly restricted and many cities were founded. From 1233 to 1411 the Margraviate was ruled by princes of the houses of Wittelsbach and Luxemburg, under whom it drifted into feudal anarchy and declined decidedly in wealth and power. In the Golden Bull of the Emperor Charles IV (1356) the Margrave of Brandenburg was recognized as one of the seven Imperial Electors. In 1411 Frederick of Hohenzollern, Burgave of Nuremberg, was given the government of Brandenburg by Sigismund and in 1415 was invested with the Margraviate and electoral dignity. Frederick and his successors crushed the nobility once for all, restored order, and extended the boundaries of their principality. The Reformation was introduced about 1540, and in the religious disputes of the succeeding period the electors of Brandenburg were leading champions of the Protestant cause. The greatness of Brandenburg may be dated from 1618, when John Sigismund became, through marriage, Duke of Prussia. In spite of the disasters of the Thirty Years' War, Brandenburg-Prussia, under the energetic rule of the Great Elector, Frederick William (1640-88), rose to the position of a leading state in northern Europe. In addition to Brandenburg and East Prussia, his dominions embraced the eastern and larger half of Pomerania, and the former sees of Halberstadt, Minden, and Magdeburg (all acquired in the Peace of Westphalia in 1648), together with Cleves, Maik, and Ravensberg, in the region of the Rhine and Westphalia. Under his son and successor, the Elector Frederick III (King Frederick I of Prussia), this realm was transformed at the very beginning of the eighteenth century (1701) into the Kingdom of Prussia, into whose history the history of Brandenburg is subsequently merged. Consult Brosen, *Geschichte der Mark Brandenburg im Mittelalter* (Leipzig, 1887), and Holtze, *Geschichte der Mark Brandenburg* (Tubingen, 1912).

BRANDENBURG (anciently, *Binnaborch* or *Brennabor*, from Slav *Brand*o, *Brann*y bor, from *brant*, war fight + *bor*i, forest). A city in the administrative district of Potsdam, in the Prussian province of Brandenburg, situated on the Berlin and Magdeburg Railway, about 37 miles west-southwest of Berlin (Map Prussia, E 2). The river Havel divides it into two parts, Old and New Brandenburg, both surrounded with walls. On an island in the river there is a third quarter, containing the castle, cathedral, and an academy for young noblemen.

There are five old churches, including the cathedral, containing interesting examples of architecture of the fourteenth and fifteenth centuries. Brandenburg has an extensive industry in the manufacture of basket ware, woollens, linen, hosiery, paper, leather, and beer. Boat building is also carried on to a considerable extent. Pop., 1900, 49,263, 1910, 53,595. Brandenburg became the seat of a bishopric as early as 949. From Nov 27 to Dec 5, 1848, Brandenburg was the seat of the National Assembly of Prussia.

BRANDENBURG, CONFESSION OF. A confession of faith prepared by order of John Sigismund, the Elector of Brandenburg, in 1614 with a view to reconciling the tenets of Luther with those of Calvin and to terminating the disputes provoked by the Augsburg Confession. It had authority in the churches of Brandenburg till the union of Lutheran and Reformed churches in 1817.

BRANDENBURG, NEU. See NEU-BRANDENBURG.

BRANDES, bran'dēs, CARL EDVARD COHEN (1847-) A Danish author, born in Copenhagen, a brother of Georg Brandes, and distinguished as a writer on dramatic and philosophic topics and as a dramatist. His best-known works are *Lagenvalder* (1881), *Helmskifte* (1880), *En Besuch* (1882), *En Bruch* (1885), *Liebe* (1887), *Under dem Gæst* (1890), *Under Loven* (1890), *Hos Sighurt* (1902), and the novels, *En Politiker* (1889) and *Das junge Blut* (1899).

BRANDES, bran'dēs, GEORG MORRIS COHEN (1842-) The first of Danish critics by genius, and one of the great systematic critics of literature in modern times, worthy to rank with the Frenchmen Sainte-Beuve, Taine, and Brunetiere. Even his books of travel are books of criticism, but it is with the wide currents of European thought that he concerns himself, rather than with any national achievements or with questions of formal aesthetics and technique. So his work at a time of national disturbance has been to preserve for the Danes a cosmopolitan intellectual horizon and a community of higher interests with their neighbors. He was born in Copenhagen, of Jewish parents, studied at the university there, traveled for several years, during which he became acquainted with many of the leaders of European thought, taught at the University of Copenhagen (1872-77), lived for five years in Berlin (1877-82), and has since resided, as a public lecturer with a subscribed guarantee of \$1000 a year, in Copenhagen. He wrote *Æsthetic Studies* (1868), *French Æsthetics* (1869), *Criticism and Portraits* (1870), *The Main Literary Currents of the Nineteenth Century* (1872-82). This was followed by *Danish Poets* (1877), *Ferdinand Lassalle* (1877, written in German), *Lord Beaconsfield* (1879, written in German), *Eminent Authors of the Nineteenth Century* (1882), *Men and Works in European Literature* (1883), *Berlin as an Imperial Capital* (1884), *Impressions of Poland* (1886), *Impressions of Russia* (1888), *Essays* (1890). His most recent works are *Poems* (1899), a remarkably fresh and sympathetic study of Shakespeare (1898), of which the English translation is in a second edition, and *Poland* (1903). Brandes is a scientific critic to whom literature is itself a "criticism of life"—a disciple of Comte and Taine, of Mill and Spencer. Naturally, therefore, he has moved in an atmosphere of controversy which has itself tended to awaken the national mind and has

given to much of his work a sort of challenging boldness. His great work, the *Main Currents* (latest ed., 1906), is in 6 vols. and gives a clear picture of the main tendencies of European literatures since the beginning of the nineteenth century. It treats first of the French "emigrant literature," revived by contact with England and Germany, at the hands of Châteaubriand, Madame de Staël, and Sénancour. From this he passes to the German romantic school, thence to the French reaction, and to what he calls "Naturalism" in England. This leads him directly to the French romanticists, and these to the so-called Young Germany beginning about 1830, with which the work has rested, great though incomplete, for many years. The collected *Works* of Brandes appeared at Copenhagen in 18 vols. (1899-1906). More recent publications are *Recollections of my Childhood and my Youth* (New York, 1906); *Erinnerungen* (1908).

BRANDING (AS, Brand, a burning, sword, Ger. a burning, brand). In Mercantile Law, the act of distinguishing goods by burning or stamping a distinctive mark into or upon them. In the case of manufactured articles, this practice has become a part of the matter of trademarks.

Branding of Animals, especially on the great ranches of the West, is commonly resorted to as a means of identification. When the cattle of various owners, who in many cases count their stock by the thousands, run on unfenced government range, the brand has been for years the only absolute proof of title and in most of the cattle States legal provision has been made for the registration and severe penalties provided for the altering of a registered brand. Calves are usually branded before they are weaned, the brand on the mother showing whose "iron" should be placed on her offspring. The brand is made on whatever part of the body may be convenient. The iron is heated to a dull red and applied just long enough to sear the hide and prevent the growth of hair. An iron too hot, or too long applied, will cause the brand to "blotch" or become illegible. Cattle thieves have developed the lucrative art of altering brands by clipping the hair, using hot wire, and branding with steam by means of a hot iron and a wet blanket. The requirements of a good brand are, that it be difficult to alter or conceal, easy to read or describe, and not so large as to disfigure and reduce the value of the hide. When letters of the alphabet are used as brands, they are often varied by the position they occupy; when tilted at an angle of 45°, they are said to be "tumbling"; when lying flat on their back or face, "lazy." See EARMARK; WATTLE.

In Criminal Law, a form of punishment employed in certain cases by the Greeks and Romans and adopted by the Canonists and by our Anglo-Saxon ancestors. In England laymen convicted of felony who claimed benefit of clergy, which exempted them from the ordinary penalties of the criminal law, were branded by burning with a hot iron in the brawn of the left thumb. As the benefit of clergy could be claimed only once, the brand, upon a subsequent conviction for felony, was evidence of the former conviction. By a statute of 21 James I. c. 6 (1623), women convicted of simple larcenies under the value of 10 shillings were burned in the hand, whipped, stocked, or imprisoned, for a first offense, instead of being executed. By later legislation (10 & 11 Wm. III. c. 23 (1699)

it was provided that such offenders should be branded on the cheek, but this barbarous enactment was repealed seven years afterward (5 Anne, c. 6). In 1695 the possession of coin clippings was made punishable by a heavy fine and by branding on the cheek. This method of punishment was practiced to some extent by the early Colonists in America, but is now obsolete, both here and in Great Britain. See BENEFIT OF CLERGY; PUNISHMENT.

BRANDIS, brân'dis, CHRISTIAN AUGUST (1790-1867). A German philosophical writer. He was born at Hildesheim. He took part in the preparations for the great critical edition of the works of Aristotle, contemplated by the Berlin Academy of Science (5 vols., Berlin, 1831-36), and with this object spent several years, along with Immanuel Bekker (q.v.), in exploring the chief libraries of Europe. In 1821 he was called to the new University of Bonn, where he edited Aristotle's *Metaphysics*, vol. i (Berlin, 1823), *Scholia in Aristotelem* (Berlin, 1830), and *Scholia Græca in Aristotelis Metaphysicum* (Berlin, 1837). He accepted in 1837 a call from the young King of Greece and spent several years in that country as Cabinet Counselor. As a result, we have his *Mitteilungen über Griechenland* (3 vols., Leipzig, 1842). Other works of his are *Handbuch der Geschichte der griechisch-römischen Philosophie* (3 vols., Berlin, 1835-66) and *Geschichte der Entwicklung der griechischen Philosophie und ihrer Nachwirkungen im römischen Reiche* (Berlin, 1862-64).

BRANDIS, SIR DETRICH (1824-1907). A German-English forester. He was born in Bonn, studied at the universities of Copenhagen, Göttingen, and Bonn, and in 1855 was appointed superintendent of the teak forests of Pegu. From that time until 1883 he was employed under the British government in the care of the forests of Burma and India, having been from 1864 inspector general of forests to the Indian government, and in 1887-90 had charge of courses on continental forestry in the Royal Indian Engineering College at Cooper's Hill, England. He completed L. Stewart's *Forest Flora of Northwest and Central India* (London, 1876), and also wrote an elaborate work on *Indian Trees* in 1906.

BRANDL, brân'dl, ALOIS (1855-). A German Anglicist, born in Innsbruck. He studied English philology in Berlin and London, was made extraordinary professor at Prague in 1884, and ordinary professor at Göttingen in 1888, at Strassburg in 1892, and at Berlin in 1895. His principal work is *Samuel Taylor Coleridge und die Englische Romantik* (1886; Eng. ed., 1887). He also contributed an interesting article on Middle-English literature to Paul's *Grundriss der germanischen Philologie*. In 1892 he became associate editor of the work entitled *Quellen und Forschungen zur Sprache und Kulturgeschichte der germanischen Völker*. He also wrote *Persönliche Eindrücke von Amerikanischen Universitäten* (1907) and *Geschichte der Allenglischen Literatur* (1908).

BRANDON. An enterprising city in Manitoba, Canada, 133 miles west of Winnipeg, on the Canadian Pacific, the Great Northern, and the Canadian Northern railways (Map: Manitoba, J 5). It is finely situated on a hill overlooking the valley of the Assiniboine and in 1912 had a good sewer system (21 miles), 42 miles of granolithic sidewalks, and stock yards of 12-carload capacity. Among the prominent institu-

tions are the courthouse, asylum for the insane, Dominion experimental farm, Indian Industrial School, and a college (Baptist). The city is an important railway centre, being a division point on the Canadian Pacific and the Canadian Northern, and has flour mills, saw mills, and grain elevators. It manufactures stove fittings, bricks, cement blocks, pumps, windmills, saddles, and threshing machines. Brandon was founded in 1881. Pop., 1901, 5620, 1911, 13,839.

BRANDON A town in Rutland Co., Vt., 15 miles north by west of Rutland, on the Rutland Railroad (Map Vermont, B 5). It has a public library and a fine high school. The chief industry of the town is the quarrying of marble. Pop., 1900, 2750, 1910, 2712.

BRANDT, brant, ENEVOLD, COUNT (1738-72). A Danish courtier. He was born in Copenhagen and studied law at the university of that city. He became assistant judge of the Supreme Court of Copenhagen in 1764, Royal Chamberlain in 1769, and afterward superintendent of the Royal Theatre. He acted as the companion of King Christian VII., but became involved in the catastrophe of Jan 17, 1772, and, together with his friend Struensee (qv), to whose advancement he had contributed, was condemned to death, his execution following on April 28, 1772.

BRANDT, HEINRICH VON (1789-1868). A Prussian general. He was born at Lakin, in West Prussia, and after pursuing legal studies in Berlin, entered the army as ensign in 1807. The Peace of Tilsit made him a subject of the Grand Duchy of Warsaw, and as such he fought in Spain and in the Napoleonic campaign in Russia. He was wounded in the battle of Leipzig and taken prisoner by the Russians, who forced him into the Polish army. He entered the Prussian army in 1816 and became a member of the general staff. He was connected with the Polish insurrections of 1831 and 1848, the latter of which he helped to suppress. He retired from the army in 1857, with the rank of general of infantry. In 1849 he had been elected to the Prussian Upper Chamber, and in the following year he was a member of the Erfurt Parliament. He was the author of a number of works on military subjects, including *Geschichte des Kriegswesens* (Berlin, 1830-35), *Grundzüge der Taktik der drei Waffen* (1833), *Der kleine Krieg* (2d ed., 1850). Consult *Aus dem Leben des General Brandt* by his son (2 vols., Berlin, 1882).

BRANDT, HENRI FRANÇOIS (1789-1845). A Swiss medalist. He was born at La Chaux-de-Fonds, Canton Neuchâtel. After a short apprenticeship he went to Paris, where he studied under David and the sculptor Bidaud and in 1812 was awarded the *Grand Prix de Rome*. In 1817 he was called to Berlin as chief engraver to the mint. Many of his medals represent important events in the history of Prussia. Though a conscientious artist and excellent in drawing, his work is somewhat cold and academic. A complete catalogue of the medals designed by him may be found in the *Publications of the Berlin Academy* for 1845.

BRANDT, HERMANN CARL GEORGE (1850-) A German-American scholar, born at Vilsen, Germany. He graduated in 1872 at Hamilton College, was an instructor there in 1874-76, and from 1876 to 1882 was associate professor of German at the Johns Hopkins Uni-

versity. In 1883 he was appointed professor of German language and literature at Hamilton. His publications include a German-English and English-German dictionary, an edition (1879) of the *Nathan der Weise* of Lessing, a *German Grammar* (1884), *German Reader* (1889), *German Science Reader* (1897).

BRANDT, JOSEF VON (1841-) A Polish historical and genre painter. He was born at Szczepieszyn, near Warsaw, and studied with Franz Adam and Piloty in Munich. Most of his pictures represent Polish military life of the seventeenth century, although several of the very best deal with the life of the Polish peasantry. They excel in the representation of movement and exuberant life, and in depicting the horses of the steppes. Among his important works are "Stefan Czarniecki and his Cavalry Crossing the Ice" (1870, Academy, Vienna), "Cossack Horses in a Snowstorm" (1885, Pinakothek, Munich), "Tartar Battle" (1906), and "The Runaway," which in 1900 received a prize in the National Academy, New York.

BRANDT, MARIANNE, family name MARIE BISCHOF (1842-) A German operatic singer. She was born in Vienna and was educated at the Conservatory in that city. She first attracted attention as Recha in *La Juive* and soon afterward accepted an engagement in Graz. From 1868 to 1886 she was associated with the Royal Opera in Berlin. In 1886 she went to New York, where she sang for several seasons the principal contralto rôles at the Metropolitan Opera House under Seidl. Gifted with a rich contralto voice of extraordinary compass and possessing exceptional histrionic gifts, Marianne Brandt was regarded, in her prime, as one of the greatest German contraltos of the century. As an admirable interpreter of Wagnerian rôles, she contributed largely to the success of the music festivals held in Bayreuth in 1876 and 1882. In 1890 she took up her residence in Vienna as a vocal teacher.

BRANDT, MAX AUGUST SCRIPTO VON (1835-) A German diplomat, the son of Heinrich von Brandt (qv), born in Berlin. After serving in the army, he was made in 1860 member of a diplomatic mission dispatched to the Far East. From 1862 to 1875 he was in Japan as a diplomatic representative, successively, of Prussia, of the North German Confederation, and of the German Empire. From 1875 to 1893 he was Minister at Peking. He wrote *Aus dem Lande des Zopfes* (1894), *Die Zukunft Ostasiens* (1895), *Sittenbilder aus China* (1895, 2d ed., 1900), *33 Jahre in Ostasien. Erinnerungen* (3 vols., 1901), *Fremde Früchte* (1904), *Der Chinese in der Familie und in der Öffentlichkeit wie er sich selbst sieht und schildert* (1912).

BRAND'Y (for older brandywine, cf. *Ger. Branntwein*, burned, distilled wine). A term sometimes applied generically to all kinds of ardent spirits, but usually restricted to the liquid obtained by distilling the fermented juice of the grape. The various fermented wines employed for this purpose contain from 7 to 13 per cent of their weight in alcohol, the white wines being preferred, as they possess a finer flavor than red wines. The yield of 1000 gallons of wine is from 100 to 150 gallons of brandy. The liquor varies in strength, but is commercially judged of according to the quantity of *eau de vie* or brandy *à preuve de Hollande* which it contains. It is generally diluted with water until it consists of from 50 to 54 per cent by

volume of absolute alcohol. When distilled, brandy is clear and colorless and will remain so if kept in glass vessels. But when placed in wooden casks the spirit dissolves out the coloring matter of the wood and acquires a light sherry tint, which dealers often make deeper by the addition of burnt sugar and other coloring matters. The pleasant aroma of brandy is due to the presence of more or less fusel oil (q.v.), accompanied by æthanolic ether. The most famous brandy is that known as Cognac, distilled in the departments of Charente and Charente-Inférieure, in the southwest of France. Because of the ravages of the Phylloxera insect, the manufacture of genuine Cognac has greatly decreased in France in recent years, while the manufacture of factitious Cognac has correspondingly increased. Brandy is also made in Spain and Portugal and, within recent years, in California. A second-class brandy is obtained from the refuse (*marc*) of the grapes left in the wine press, the scrapings of wine casks and vats, and the deposits of wine bottles. Very much of the brandy of commerce is a factitious product made from grain or potato spirit. In America brandy is made not only from fermented grapes, but also from apples (see **APPLE BRANDY**), pears, cherries, and peaches. For the production of brandy in the United States, see **LIQUORS, FERMENTED AND DISTILLED, STATISTICS OF**. See also **DISTILLED LIQUORS; ALCOHOL; ALCOHOL, PHYSIOLOGICAL EFFECTS OF**.

BRANDY STATION. A village in Culpeper Co., Va., about 56 miles southwest of Alexandria (pop., about 225), the scene of considerable fighting during the Civil War. Engagements between Federal and Confederate forces occurred here on Aug. 20, 1862, when the Federals made a notable cavalry charge; on June 9, 1863, when the Confederate general, Stuart, at the head of a cavalry force of about 10,000, won a tactical victory over a somewhat inferior force of Federal cavalry under Generals Pleasanton and Buford, the former losing 485 in killed, wounded, and missing, the latter, 907; on Sept. 13, 1863, and on Oct. 11, 1863. Various other skirmishes of minor importance were fought in this vicinity during the Chancellorsville and Gettysburg campaigns. The engagement of June 9, 1863, was of considerable strategic importance. It is often called the battle of Beverly's Ford.

BRANDYWINE, BATTLE OF. A battle fought at Chadd's Ford, Pa., on the Brandywine Creek, Sept. 11, 1777, during the American Revolution, between about 18,000 British under General Howe, and about 11,000 Americans under General Washington. Half the British army under Lord Cornwallis turned the right flank of the Americans by a forced march of 18 miles along the Lancaster Road, and drove back the American right under General Sullivan, while Knyphausen, with the other half, crossed at Chadd's Ford and forced the American centre and left, under Greene and Wayne respectively, back towards Dilworth and Chester. The Americans, though defeated, withdrew in good order, and the three divisions safely effected a junction at Chester. The American loss was estimated at about 1000, the British at about 600. Howe's victory enabled him to occupy Philadelphia, with little resistance, on the 26th, the Continental Congress adjourning first to Lancaster and then to York. Lafayette was severely wounded in this engagement. Consult Carrington, *Battles*

of the American Revolution (New York, 1877); Edward Channing, *History of the United States*, vol. iii (New York, 1912).

BRANFORD. A borough in a town of the same name, New Haven Co., Conn., 8 miles southeast of New Haven, on Long Island Sound, and on the New York, New Haven, and Hartford Railroad (Map: Connecticut, D 4). It manufactures malleable iron fittings, and wire. Oyster culture, fruit raising, and granite quarrying are carried on. The borough is a popular summer resort and contains the Blackstone Memorial Library. Branford, originally called Totoket, was settled in 1644 by a company from Wethersfield, Conn., which was soon afterward joined by another company, headed by Rev. Abraham Pierson (q.v.), from Southampton, L. I., and derived its later name from Brentford, England. In 1667 many of the settlers, dissatisfied with the union of the Connecticut and New Haven colonies, moved in a body to Newark, N. J., but others soon came in and took their places. In 1685 Branford received its patent from the Colony. North Branford was set off in 1831. The borough was incorporated in 1893. Pop. (town), 1900, 5706; 1910, 6047; (borough), 1900, 2473; 1910, 2560. Consult Rockey, *History of New Haven County* (New York, 1892).

BRANGWAINE. The nurse of Yseult in the legend of *Tristan and Yseult*, modifications of which may be found in poems of Matthew Arnold, Swinburne, and Tennyson. In Wagner's music drama of *Tristan and Isolde* the spelling is Brangäne. She is, originally, the "Venus of the Northern Seas."

BRANGWYN, FRANK (1867-). An eminent English painter, etcher, and illustrator, born in Bruges. He studied in the South Kensington art schools and in the studio of William Morris, and afterward traveled extensively in the East. He paints broadly and freely, his color is vivid, and the subject is always subordinated to the general scheme of line and color. His etchings are conceived in surfaces and not in lines, with sharp contrasts of light and shade. Brangwyn is considered by many critics the most prominent and versatile master in contemporary British art. Among his large decorative works are mural paintings, illustrating "Modern Commerce," in the Royal Exchange, London, and a mural painting 50 feet long ("King John Signing the Magna Charta"), for the courthouse at Cleveland, Ohio. He was commissioned to decorate the East Pavilion at the Panama Exposition of 1915. His paintings include "The Convict Ship," "Burial at Sea" (Glasgow), "Venetian Funeral" (Leeds), "The Baptism of Christ" (Stuttgart), and "Mars and Venus" (Dublin). Among his etchings are "Old Houses, Ghent," "London Bridge," "The Sawyers," "The Building of Kensington Museum," and "The Paper Mill." An exhibition of his etchings was held in the Public Library, New York, 1914. He became president of the Royal Society of British artists and a member of the Royal Academy. The best monograph is by Shaw-Sparrow, *Frank Brangwyn and His Work* (London, 1910).

BRANICKI, bra-nits'ké, JAN CLEMENS (1689-1771). A Polish hetman, a great-grandson of the celebrated Czarniecki, and the last of a distinguished line of nobles. After a period of service in the French army, he returned to Poland, where in 1715 he joined the league against Augustus II. He became successively starost, standard bearer, hetman (1735), waywode

of Cracow (1746), and grand hetman (1752), and upon the death of Augustus III, encouraged by expectations of French support, he sought the crown of Poland, but the monarchical party represented by the Czartoryski controlled the Polish Diet of 1764, and by their command Branki was seized, deprived of all his honors and dignities, and banished from the country. He fled to Hungary, but returned upon the accession to the throne of his brother-in-law, Poniatowski, and thereafter lived in retirement on his estate.

BRANK (probably akin to *Ir brancas*, halter, pillory, Dutch *pranger*, fetter), or **SCOLD'S BRIDLE**. An instrument formerly used in England and Scotland for the punishment of notorious scolds and of women convicted of street brawling or of insulting public officers. It was an iron framework which was placed on the head, inclosing it in a kind of cage. In front

BRANK

was an iron plate, sometimes covered with spikes, which entered the culprit's mouth and prevented the use of the tongue. With this riddle on her head, the victim was led through the streets or chained to a pillory or market cross. On market days the instrument was exhibited in front of the house of the officer authorized to use it, as a warning to vixens. In some parts of Britain it continued to be used well into the last century. Its history is old and its various forms illustrated in Andrews, *Old-Time Punishments* (London, 1890). Consult also Earle, *Curious Punishments of Bygone Days* (Chicago, 1896).

BRANLE, *brân'l'*. An old French dance of the sixteenth and seventeenth centuries. It is written in 4-4 time, in moderate tempo, and always begins on the down beat.

BRAN'NAN, JOHN MILRON (1819-92). An American soldier. He was born in the district of Columbia, graduated at West Point in 1841, and in 1847, during the Mexican War, participated as first lieutenant in the various battles of the Southern campaign. In September, 1861, he was appointed brigadier general of volunteers and from January to March, 1862, commanded the Department of Key West. He served from June, 1862, to January, 1863, in the Department of the South, of which he was twice temporarily in command, and during this time commanded the St. John's River expedition (September, 1862), and took part in the battle of Pocotaligo during the Tennessee campaign of 1863. He commanded a division, participated in the battles

of Chickamauga and Chattanooga, and from December, 1863, to May, 1864, was engaged in reorganizing the artillery of the Army of the Cumberland. From May to October, 1864, he took part in the invasion of Georgia, and after the capture of Atlanta arranged the artillery for the defense of that place. At the close of the war he was brevetted major general of volunteers and both brigadier general and major general in the regular army, and subsequently served at various army posts, as lieutenant colonel and colonel, until 1882, when he retired from active service.

BRAN'NER, JOHN CASPAR (1850-) An American geologist and educator, who in 1913 became president of the Leland Stanford Junior University. He was born at New Market, Tenn., studied at Cornell University, and in 1875-77 was a member of the Imperial Geological Commission of Brazil. From 1882 to 1883 he was agent in Brazil for the United States Department of Agriculture, and from 1883 to 1885 Topographical Geologist of the Pennsylvania Geological Survey. He was appointed professor of geology at the University of Indiana in 1885, in 1892 was called to a similar chair at the Leland Stanford Junior University. From 1887 to 1893 he was State Geologist of Arkansas and in his official capacity was an important factor in the development of the mineral resources of that State. In 1899 he directed a geological expedition to Brazil and in the same year was appointed vice president of the Leland Stanford Junior University. He was special assistant of a geological survey of Brazil in 1906-07 and directed a second scientific expedition to that country in 1911. Among his publications are *Annual Reports of the State Geologist of Arkansas* (1887-1901), "Cotton in the Empire of Brazil," *United States Department of Agriculture, Miscellaneous Special Reports* (1885), "Bibliography of Clays and the Ceramic Arts," *United States Geological Survey Bulletin, No. 143* (1896), *From School to College* (1905), *Geologic Work of Ants in Tropical America* (1911).

BRANT (probably refers to the dark color, meaning something burnt, of *brand*). The name given to various species of goose of the genus *Branta*. The brants may be recognized by the black cheeks and chin taken in connection with the white patches or streaks on the sides of the neck. They are considerably smaller than the common wild goose, and fly less rapidly, in more compact groups, and without a chosen leader. The common brant (*Branta bernicla*) is found throughout the northern portions of the whole Northern Hemisphere. It breeds in the far north, well within the Arctic Circle, but migrates southward in Europe and eastern North America on the approach of winter. The nest is made on the ground, from grasses, moss, etc., and is lined with feathers. The eggs are said to be creamy white in color and only four in number. The brant, though occasionally seen in the interior of the United States, is chiefly marine, and is most abundant in shallow bays along the coast, rarely as far south as the Carolinas. It is rather sluggish in its movements, seldom taking to flight unless alarmed. It rises from the water slowly, and often returns to the same point whence it started, unless attracted by another flock. It feeds chiefly on vegetable matter, the so-called "eelgrass" (*Zostera*) furnishing a large part of its diet. It pulls this

at low tide, diving and tearing it up with its beak; and then, as the tide rises and it has to give up this method of work, it floats lazily on the water, enjoying the feast which it has earned. For the eelgrass, when pulled, floats, and so the bird can feed on it at leisure after the water is too deep for agreeable diving.

In the western part of the United States the common brant is replaced by the black brant (*Branta nigricans*), in which the lower breast and upper part of the belly are nearly as dark as the back. The black brant breeds with the common brant in the Arctic regions; but in migrating southward it resorts to the Pacific Coast and the Western States and is rarely seen in the East. The name is sometimes given to other species of goose, and the common brant is often confused with the barnacle goose (q.v.)—a very rare, accidental visitant in the United States. The snow goose (q.v.) is sometimes called "white brant," but it is not properly a brant, which it resembles only in size. See GOOSE, and PLATE OF DUCKS (WILD).

BRANT, JOSEPH (THAYENDANEGEA) (c.1742–1807). A celebrated Mohawk Indian chief. When very young he became a favorite of Sir William Johnson, who sent him to Dr. Eleazar Wheelock's school, at Lebanon, Conn., out of which later grew Dartmouth College. Here he obtained a fair education and joined the Episcopal church, of which he remained a member throughout life. For some time he was a missionary among the Mohawk Indians, and he translated into their language the Prayer Book and parts of the New Testament. He was early distinguished for his physical prowess and rendered valuable services to the English in both the French and Indian and the Pontiac wars. In 1774 he became the secretary of Guy Johnson, superintendent of Indian affairs, and throughout the Revolutionary War he served against the Americans, leading numerous sanguinary raids, participating in the Cherry Valley and Minisink massacres and taking an active part in the battle of Oriskany. He was not, however, present at the Wyoming massacre, as he is represented to have been in Campbell's *Gertrude of Wyoming*; and he seems for the most part to have treated his captives with great humanity and to have steadfastly opposed and, wherever possible, prevented torture. After the war he used his influence to preserve peace between the various Indian tribes and the whites. In 1786 he visited England, where he was entertained by many persons of prominence and became acquainted with such men as Burke and Sheridan. With money collected on this trip he built the first Episcopal church erected in Upper Canada. John Fiske has said of Brant that he "was perhaps the greatest Indian of whom we have any knowledge," and that "certainly the history of the red men presents no more many-sided and interesting character." Consult: Stone, *The Life of Joseph Brant-Thayendanegea, Including the Indian Wars of the American Revolution* (new ed., Albany, 1865); Eggleson and Seelye, "Brant and Red Jacket" in *Famous American Indians* (New York, 1879); Macdonnell, "Brant and the Butlers" in the *University Magazine*, vol. vii (Montreal, 1908).

BRANT, or BRANDT, BRÜNT, SEBASTIAN (c.1458–1521). A German satirist and humanist. He was born in Strassburg, the son of a wealthy burgher. He studied philosophy and jurisprudence at the University of Basel, taught

and practiced law there, and removed to Strassburg, where he became town clerk in 1501, in which office he served his native city well till his death. From Emperor Maximilian he received a title and a pension. He took an important part in negotiations with the Holy See. Brant achieved fame through his satirical poem, *Das Narrenschiff* ('The Ship of Fools'), published in 1494, one of the most remarkable and popular books of the time. The dialect is Alsatian and the form the short-rhymed couplet. *The Ship of Fools* (Narrenschiff) is supposed to have suggested Erasmus' famous *Praise of Folly* and was a sort of *Pilgrim's Progress* to its generation. It was a mirror to those perplexed times, and in Locker's Latin translation it was carried far beyond the borders of Germany. Neither the fiction of the ship nor the treatment of it was entirely new, but the great popularity of the book came perhaps from the very general character of the satire scourging alike real sin and innocent error, from the fortunate placing of the numerous and pointed woodcuts, and from the many well-chosen quotations from Scripture and from Latin authors. He invites to passage in his "Ship of Fools" representatives of every class—the misers, the gluttons, the churchgoers for show and the churchgoers for respectability, the pedantic and the frivolous, "from beardless youth to crooked age," knights and ladies, cooks and butlers, gamblers, drunkards, spendthrifts, merchants, alchemists, and lovers, in motley and ever-changing throng. So all classes saw themselves in his picture and read with a twinge at their own and a smile at others' folly, "the first printed book that dealt with contemporary events and living persons, instead of old German battles and French knights" (Max Müller). But Brant was no poet, nor did he have much milk of human kindness in his chastisement of poor mortals. Contemporary writers made constant allusions to it; monks preached from its texts; fifteen years after its appearance it was done into English by Barclay (London, 1609), and again by Henry Watson, as *The Grete Shyppe of Fooles of the Worlde* (1517). Barclay's edition has been edited by Jamieson (Edinburgh, 1874). The best German editions are by Zarneke (Leipzig, 1854), with an extensive commentary, and popular editions by Goedecke (Leipzig, 1872) and Bobertag in *Kürschner's Nationalliteratur*. Consult Claus, *Rhythmik und Metrik in Sebastian Brants Narrenschiff* (Strassburg, 1911).

BRANTFORD. The chief city and the county seat of Brant Co., Ontario, Canada, 70 miles east of London, on the Grand Trunk, the Michigan Central, the Canadian Pacific, and other railways, and on the Grand River (Map: Ontario, C 4). The city has fine buildings and churches and a public library and is the seat of the Ontario Institution for the Education of the Blind. It is best known as the home of the telephone, Professor Bell having invented the instrument at Tutela Heights, near the city. The manufacturing interests are extensive, the most important products being agricultural implements, engines, wagons, envelopes, paper boxes, bricks, felt and rubber goods, foundry products, engines and boilers, etc. The industries number more than 70. The town is supplied with natural gas and with electric power from Niagara Falls. The United States has a consular agent here. The city was named after the famous Mohawk chief Thayendanegea, Joseph Brant, to whom a fine monument was

erected in Victoria Square in 1887 Pop, 1901, 16,619, 1911, 23,132

BRANTÔME, bran'tom', PIERRE DE BOURDEILLES, ABBE DE (c1540-1614). A French courtier and chronicler. He was born in Perigord, and as the third son of a nobleman he was dedicated in youth to the Church, but presently became a page of the liberal and literary Margaret of Navarre. On her death (1549) he studied in Paris, served Francis of Guise, and became gentleman of the chamber to Charles IX. Then, with the exception of time spent in diplomatic missions, of which the escort of Mary Stuart to Scotland is noteworthy for the fine description that he gives of it, and in campaigns and traveling for pleasure, he passed his life at the courts of Henry III and IV, till his retirement to his ancestral estate (1594). Here lawsuits with monks and neighbors occupied his last years, and he relieved himself from the ennui they caused by reminiscent memoirs, *Vies des hommes illustres et des grands capitaines français*, *Vies des dames illustres*, *Vies des dames galantes*, *Anecdotes touchant les duels*, *Rodomontades et jurements des Espagnols*, a Life of his father, a funeral oration on his sister-in-law, and some insignificant verses. His manuscripts were not printed until 1865. The best of many editions is by Lalanne (10 vols., 1885-81). Brantôme recognizes only two social essentials—to be born an aristocrat and to hate Huguenots. Indifferent to honor and morality, he is an impartial witness to the vice and crime of his epoch. None has mirrored more truly the Valois court or its terribly depraved moral ideals. Consult Lalanne, *Brantôme, sa vie et ses écrits* (Paris, 1897). In 1904 the Ecole des Chartes collected all Brantôme's manuscripts. Consult also K. P. Wormeley's translation of Brantôme's *Illustrious Dames of the Court of the Valois Kings* (New York, 1912).

BRAS/DOR'S OPERATION. It is stated in the article ANEURISM that a cure is effected in that disease by successive layers of the fibrin of the blood being deposited in the aneurismal sac. It was suggested by Brasdor, an English surgeon, that the course of the blood should be impeded by a ligature upon the artery beyond the aneurismal sac. Brasdor, in 1826, first performed the operation successfully. See ANEURISM.

BRASE/NOSE COLLEGE. A college at Oxford, England, founded about 1509 by William Smith, Bishop of Lincoln, and Sir Richard Sutton—the last of the pre-Reformation colleges. The name is said to have come from *Brassenhus* (brewhouse), a building which previously stood on the site, and the corruption becomes at once facetious and plausible from the significant knocker, in the form of a brazen nose, which hangs over the old entrance. The new buildings on the High Street are among the best examples of modern collegiate architecture. The college accommodates about 150 undergraduates. Among its members have been Burton (author of the *Anatomy of Melancholy*), Ashmole (founder of the Ashmolean Museum), Foxe (author of the *Book of Martyrs*), Bishop Heber, Dean Milman, and Barham (author of the *Ingleby Legends*). Here, too, Walter Pater was tutor. Besides good standing as a college, Brasenose has been fortunate in her athletics, particularly boating.

BRASHEAR, brash'er, CITY. See MORGAN CITY.

BRASIDAS (Gk *Bpasidas*). A distinguished

Spartan general of the fifth century B.C., especially notable for his courageous conduct in the Peloponnesian War. For his successful relief of Methone, in Messenia, under siege by the Athenians (431 B.C.), he was made a chief magistrate of Sparta. He brought relief in 424 to Megara and, marching through Thessaly, subdued a number of Macedonian cities. Under great disadvantages he won, in 422, a signal victory over Cleon (qv) at Amphipolis, but both generals were mortally wounded. He was buried within the walls of Amphipolis. He was long honored there as a hero, and his memory was celebrated in yearly games and sacrifices. To his worth his enemies bear witness. Thucydides extols his civic virtues, and Plato mentions him with Achilles.

BRASS (AS *bras*, probably related to Icel *brasa*, to harden by fire, Swed *brasa*, to fire). An alloy of copper and zinc, considered the most important of all alloys. It was distinctly known to the ancients, as shown by its mention in the Old Testament and in the works of Pliny, though, according to some authors, the alloy of the ancients was a variety of bronze, or a mixture of copper and tin. Natural brass was early used and was known as *orichalcum*. During the Middle Ages brass was made in Germany, chiefly in sheets, which found extensive use in churches. The original method for its production, called the *cementation process*, was by heating copper in the form of shot or sheet in crucibles in contact with zinc, or with calamine and carbon, resulting in the volatilization of the zinc and its subsequent absorption by the copper. The brass thus obtained was melted down and cast. In 1781 a process for the direct production of brass from copper and zinc was patented by James Emmerson, whose method has since entirely superseded the old process, owing to its greater simplicity. Emmerson's method consists essentially in first melting the copper in a crucible, then adding the zinc in small quantities, and stirring until the two metals are thoroughly mixed, after which the molten brass is cast into molds of sand or iron. Brass has a fine yellow color, which becomes darker as the proportion of copper is increased, and is capable of receiving a fine polish. It is harder than copper and hence better adapted to resist wear. Brass is both malleable and ductile and therefore may be rolled into thin sheets or drawn into fine wire. It resists the influence of the atmosphere better than copper, but tarnishes if not protected by a lacquer or varnish. Brass comes into commerce chiefly as cast, sheet, wire, and tubes. The proportions of its two constituents vary from 10 parts of copper and 1 of zinc, forming a reddish-yellow brass, all the way to 1 part of copper and 5 parts of zinc, forming a very dark-gray alloy. The composition of brass is regulated with a view to the purpose for which the alloy is to be employed. The proportions of the more important kinds are as follows: *Button brass*, 8 parts copper with 5 parts zinc, *fine brass*, 2 parts copper with 1 part zinc, *fine casting brass*, 90 parts copper, 7 parts zinc, 2 parts tin, and 1 part lead, *gilding brass*, 64 parts copper, 32 parts zinc, 3 parts lead, 1 part tin, *malleable brass*, 3 parts copper with 2 parts zinc, *soldering brass*, 12 parts fine brass, 6 parts zinc, 2 parts lead, *wire brass*, 72 parts copper, 28 parts zinc. Some of the most important kinds of brass have special names, thus *Auch's metal* is brass composed of 60 parts

copper, 38.2 parts of zinc, 1.8 part iron; *bath metal* is 5 parts of copper and 1 part of zinc, *Bristol brass*, 61 parts of copper, 39 parts of zinc, *orovide*, or *French gold*, 9 parts copper, 10 parts zinc; *Mannheim gold*, 2 parts of copper, 1½ parts zinc; *Muntz's metal*, 10 parts copper and 12 parts zinc; *Pinchbeck*, 88.8 parts copper, 11.2 parts zinc; *Prince's metal*, 75 parts copper and 25 parts zinc; *similar*, from 6 to 9 parts of copper with 1 part of zinc. An excellent brass solder consists of equal parts of copper and zinc, 1 part of silver being added for finer kinds of work.

BRASS, SALLY. A character in Dickens's *Old Curiosity Shop*, who delighted in starving the Marchioness. She was an abler scoundrel than her brother and affected masculine ways and attire. She and Dick Swiveller struck up a curious negative sort of friendship.

BRASS, SAMPSON. The brother of Sally Brass in *The Old Curiosity Shop*, by Dickens. He was Quilp's legal tool and could either bully or cringe, as occasion required. His attempt to ruin Kit, however, resulted in his own and his sister's downfall.

BRAS-SARTS (Fr. *brassart*, from *bras*, arm, Eng. *brace*). Parts of plate armor used to protect the upper part of the arms and to unite the shoulder and elbow pieces. When half of the upper arm only was shielded, the pieces were called *demibrassarts*. Brassarts was sometimes used to designate the whole protection for the arm.

BRASSES, SEPULCHRAL OR MONUMENTAL. Flat tombstones, partly or wholly of metal, used generally during the thirteenth and following centuries. They were set in the pavements of churches and were made of brass or of a mixed metal called *latten* (Fr. *laiton*), the design being marked by incised lines in the metal, filled in with a black or dark resinous enamel. The brilliancy of the metal was sometimes enhanced by gilding and damascening. These sepulchral slabs were of two classes:

(1) Marble or stone slabs to which the brass ornamentation was attached as to a ground, the brass forming the figure of the deceased in the centre of the slab, as well as the ornaments, framework, armorial bearings, and inscription, each inserted as a separate piece of metal into cuts (or casements) made in the stone ground. (2) Slabs entirely of metal, which appear to be of a single piece, but are really composed of several sheets carefully joined, and decorated in the same style as the first class. Such brasses were used almost exclusively in England and Flanders, very seldom in Germany and northern France, not at all in Italy. Those of the first class alone were common in England; those of the second, which were far rarer, more artistic and expensive, are found mainly in Flanders, where they were produced as late as the seventeenth century, and they alone have the rich, detailed ornamentation in damascened work. The works of this sort in France have been barbarously destroyed. In England many remain. There the earliest are among the most artistic—those of Sir John d'Aubernoun at Stoke Dabernon (1277), of Sir Roger de Trumpington at Trumpington (1280), and of Sir Richard de Buslingthorpe at Buslingthorpe (1290), all very similar in style. More advanced Gothic is the 1325 slab of Sir John de Creke at Westley Waterless. England probably owed most of such works to artists from Flanders, the north of

France, and Burgundy. Among the fine sepulchral brasses in the cathedral of Bruges, that of Sire Martin de la Chapelle (1452) is a beautiful example of the damascened work. There is a close relation between the sepulchral brasses and other and earlier kinds of work, especially the bronze church doors of Byzantine art in which the design was made out in the same way by incised lines filled with enamel (see *Door*), and also the plain marble funeral slabs, common throughout Europe, especially Italy, where the design was similarly outlined. (See *Tomb*.) In a few cases the brasses were not set flush with the pavement, but were either set up vertically against the wall or raised on a basement like a simple cenotaph. They must not, then, be confounded with sepulchral monuments in cast bronze.

Bibliography. Among *Manuals* for the study of the subject are those of Haines (2 vols., London, 1861) and Macklin (ib., 1890). For the *Monumental Brasses of England*, consult the works of Boutell, with folio wood engravings (London, 1840), Waller (ib. and Oxford, 1803), and Macklin (ib., 1907). Those of many of the counties have been separately published. For *Continental Brasses* consult the published facsimiles by Cremy (ib., 1880).

BRASSEUR DE BOURBOURG, brá'sér' de bô'r'bô'r', CHARLES ETIENNE, ABBÉ (1814-74). A missionary and archaeologist. He was born in Bourbourg, France, went to the United States in 1846, and was for a time Catholic vicar-general at Boston. Two years later he entered upon his missionary labors in Mexico and Central America, which continued in connection with his studies of the ancient civilizations of that region until 1864, in which year he served as archaeologist to the French expedition to Mexico. His numerous published works were compiled from materials gathered in the field and from studies of ancient manuscripts in the archives of Madrid. Besides his monumental *History of the Civilized Nations of Mexico and Central America during the Centuries Anterior to Christopher Columbus*, published in Paris, 1867-69, he is the author of numerous linguistic, archaeological, and historical works relating to the same region.

BRASSEY, THOMAS (1805-70). An English surveyor, widely known as a railway promoter of great capacity and enterprise. At the age of 16 he became apprentice to a surveyor, who later set him up in business. His first railway contract was for a portion of the Grand Junction; then he completed the London and Southampton, with contracts involving \$20,000,000. In 1840, with a partner, he built the railway from Paris to Rouen, and was concerned in five other French lines and as many in England. The capital involved in his contracts at this period was equal to \$175,000,000. He also built railways in Holland, Prussia, Spain, and Italy, and then undertook the Grand Trunk of Canada, 1100 miles in length, with the great bridge over the St. Lawrence at Montreal. Subsequently his labors were found in almost every country in Europe, India, Australia, and South America. Although he received many honors, he was modest and simple in his tastes and manners. Consult Sir Arthur Helps, *Life and Labors of Mr. Brassey* (London, 1872).

BRASSEY, THOMAS BRASSEY, G.C.B., first EARL (1836-). An English politician, son of Thomas Brassey (q.v.). He was born at Staf-

ford, England, and was educated at Rugby and at University College, Oxford, graduating with honors. He was elected to Parliament for Devonport in 1865, represented Hastings from 1868 to 1886, was appointed Civil Lord of the Admiralty in 1880 and was secretary to the Admiralty in 1883-85. He was Governor of Victoria from 1895 to 1900 and became Lord Warden of the Cinque Ports in 1908, a post which he resigned in 1913. He founded *Brassey's Naval Annual* and wrote *Work and Wages* (1872), *The British Navy* (5 vols., 1882-83), *Lectures on the Labor Question* (1878), *Sixty Years of Progress* (1904, 3d ed., 1912). His first wife, Lady Anna (Allnutt) Brassey, accompanied him on his journey around the world and published *The Voyage of the "Sunbeam"* (1877), *Sunshine and Storm in the East* (1878), *The Trades, the Tropics, and the Roaring Forties* (1884). She died at sea, 1887.

BRASSICA See CABBAGE

BRATHWAITE (also BRATHWAIT), RICHARD An English poet (1588-1673), educated at Oxford and Cambridge, lived in London and Westmoreland, his native county. Among his numerous volumes of verse are: *The Golden Fleece* (1611), *The Poet's Willow*, pastorals (1614), *A Stappado for the Devil*, satires (1615), *Nature's Embassy*, odes and pastorals (1621), and the long-popular *Barnabee's Jurnall* (1638), in English and Latin doggerel, famous for the Puritan who hanged his cat on Monday for killing a mouse on Sunday. Consult *Barnabee's Jurnall*, ed. Hazlitt (London 1876), *Law of Drunkenness* (New Haven, 1903). Brathwaite has been the subject of a vast number of monographs, of which a bibliography, completed to 1876, was made by Haslewood and Hazlitt.

BRATTIANU, bra-ti-an', JOAN (1821-91). A Rumanian statesman. He was born at Pitești and studied in Paris, where he took an active part in the student gatherings and republican manifestations which preceded the Revolution of 1848. Soon after his return to Bucharest he became one of the active instigators of the revolution which led to the deposition of the hospodar, George Bibesco. His radicalism and his prominence in the provisional government led him to advocate independence and oppose all schemes which had for their aim the placing of Wallachia under a Russian protectorate. In the same year, when repressive steps were taken by Russia and Turkey, he was seized, with several other leaders of the revolutionary party, and for 15 days retained as a prisoner upon a miserable bark on the Danube. Condemned to exile, he returned to Paris, where he remained until the affairs of the Danubian principalities had been adjusted in the Peace of Paris (1856). Upon the accession of Prince Charles of Hohenzollern to the Rumanian throne, Brattianu became Minister of State, but was compelled to resign in 1868. Reinstated in 1876, he entered into an alliance with Russia against Turkey in 1877, proclaimed the independence of Rumania, May 21, 1877, and its establishment as an independent kingdom, March 26, 1881. In 1883 he resigned as President of the Ministry, his fall being largely due to the intrigues of his brother Demeter, who succeeded him. His writings include *Mémoire sur l'empire d'Autriche dans la question d'Orient* (1855), and *La question religieuse en Roumanie* (1866).

BRATSCHKE, brát'she The German name for the viola. (q.v.)

BRATTIA See BRAZZA

BRATTICE (OF *bietsche*, *bietsche*, Ger *Brat*, AS *bied*, board, plank) The term applied to any partition erected for deflecting air currents in mines. Such partitions are more commonly used in coal than in metal mines. The partition is usually made of thin boards or of canvas and is erected along an entry or room dividing it into two air ways so that the fresh air will be obliged to travel on one side of the brattice and the air contaminated with gas or smoke will travel on the other side to the exhaust. A temporary brattice is often constructed by nailing brattice cloth or heavy duck canvas to upright posts set from 4 to 6 feet apart along one side of an entry a short distance from the rib or pillar.

BRATTLEBORO, brát'tl-bór'ò A village, in a town of the same name, in Windham Co., Vt., on the Connecticut River, 80 miles north of Springfield, Mass., and on the Boston and Maine and the Central Vermont railroads (Map Vermont, D 8). It has a picturesque site and contains a fine public library and a Retreat for the Insane, a Home for the Aged and Disabled, and the Austine Institution for the Blind, Deaf, and Dumb. The principal manufactures include children's carriages and toys, furniture, overalls, shoe lasts, stamping and sealing machines, cotton goods, and organs, the factories of the Estey and Carpenter organ companies being situated here. Brattleboro was chartered in 1753 and derives its name from William Brattle of Massachusetts, one of the original grantees. Pop., 1900, 5297, 1910, 6517. Consult Burnham, *Brattleboro* (Vt.) *Early History with Biographical Sketches* (Brattleboro, 1890), Howard, *Brattleborough in Verse and Prose* (Brattleboro, 1885).

BRATTON, HENRY DE See BRACTON

BRAUN, broun, ALEXANDER (1805-77). A German botanist. He was professor of botany in the universities of Freiburg, Giessen, and Berlin, successively, and was director of the Berlin Botanical Garden. Although he contributed largely to our knowledge of the morphology of many groups, all of his writings are permeated with the idealistic nature philosophy of his time. His influence as a teacher was very great, and as an investigator he stood in the first rank. Consult Mettemeyer, *A Brauns Leben* (Berlin, 1882).

BRAUN, AUGUST EMIL (1809-56). A German archaeologist, born in Gotha. He studied in Göttingen, Munich, Berlin, Dresden, and Paris. With Gerhard he went to Rome in 1833, and in a short time was made librarian and subsequently secretary of the Archaeological Institute. Later he founded there a galvanoplastic establishment, from which issued many reproductions of antique art objects and casts of modern works. Among his many valuable works on art may be mentioned *Il giudizio di Paride* (1838), *Kunstvorstellungen des geflügelten Dionysos* (1839), *Antike Marmorwerke* (1845), *Griechische Götterlehre* (1851-55), *Vorschule der Kunstmythologie* (1854, Eng. trans. by Grant, 1856), and an admirable guidebook, *Das Römische und Museen Roms* (1854, Eng. trans., 1856).

BRAUN, FERDINAND (1850-) A German physicist, born at Fulda, and educated at the Fulda gymnasium and the universities of Marburg and Berlin. From the latter he received the degree of Ph.D. in 1872 with a dissertation on the vibration of cords. For some years

he filled various academic positions at the universities of Würzburg, Marburg, Strassburg, and Tübingen (where he was professor of physics for a decade). In 1895 he became professor of physics and director of the Physical Institute at the University of Strassburg, and there he remained in spite of a call to succeed the late Gustav Wiedemann (q.v.) at Leipzig. With Marconi he received the Nobel prize for physics in 1909. His researches in electricity resulted in a cathode ray tube and many improvements in radio-telegraphy, especially by making use of the principle of resonance to effect syntonization in the circuit. In 1902 he discovered a method for increasing at will the energy of the sending station; and he succeeded in gaining control of the direction of the effective radiation by the arrangement of the antenna. His many improvements in wireless telegraphy were acquired by the Telefunken Company as a part of their extensive system of patents. His researches were also concerned with the electro-magnetic theory of light and with fine metallic gratings. See WIRELESS TELEGRAPHY.

BRAUN, JULIUS (1825-69). A German archaeologist. He was born in Karlsruhe and studied at the universities of Heidelberg and Berlin. At first a lecturer in the University of Heidelberg, he afterward went to Tübingen and finally to Munich, where he lectured in the Academy of Arts. Both in his books and in his lectures he maintained the thesis that the really fundamental principles of art and religion were derived from the Egyptians and were transmitted, through the Semites, Greeks, and Romans, to the Germanic and other northern peoples. He wrote: *Studien und Skizzen aus den Ländern der alten Kultur* (1854); *Geschichte der Kunst in ihrem Entwicklungsgange, etc.* (1873); *Naturgeschichte der Sage* (1865); *Historische Landschaften* (1867); *Gemälde der mohammedanischen Welt* (1870).

BRAUN, KARL (1822-93). A German statesman and author. He was born at Hadamar, in the Duchy of Nassau, and studied classical philology and history at Marburg, and law and political economy at Göttingen. He was president of the Nassau Chamber of Deputies from 1859 to 1866, and as the leader of the Liberals advocated German unity and industrial freedom. He was one of the founders of the *Volks-wirtschaftlicher Kongress* and was elected its permanent president in 1859. In 1863 he established the *Vierteljahrsschrift für Volkswirtschaft und Kulturgeschichte* and edited this publication until 1887. As a deputy in the Reichstag he was successively identified with the National Liberal, Secessionist, and German Liberal parties. Among his works are the volumes entitled *Bilder aus der deutschen Kleinstaaterei* (5 vols., 3d ed., 1881), his most famous work, and also *Mordgeschichte* (2 vols., 1874); *Eine türkische Reise* (3 vols., 1876-78).

BRAUN, KASPAR (1807-77). A German wood engraver and draughtsman. He was born at Aschaffenburg and studied at the Academy in Munich, where he began as a painter of fantastic landscapes and genre pictures. After experimenting with various techniques he turned to wood engraving and in conjunction with Desauer established the xylographic institute in Munich, which soon became celebrated and counted among its students a large number of the greatest modern German wood engravers. With Friedrich Schneider he established in 1843

the famous firm which published the numerous periodicals *Fliegende Blätter*, the *Leipziger Illustrierte Zeitung*, the *Münchener Bilderbogen*, and many other publications to which prominent German artists contributed their drawings.

BRAUN, LOUIS (1830-). A German battle and genre painter. He was born at Schwäbisch Hall, Württemberg, and studied painting in Munich under his brother and Bernhard Nelsner, and in Paris under Horace Vernet. He took part in the Danish War of 1864, in the Austro-Prussian War of 1866, and the Franco-German War of 1870-71. The studies he was thus able to make were afterward worked up into large pictures of historic truthfulness and picturesque effect, such as: "The Market Place of Attigny" (Museum of Königsberg), "The Entrance of the Germans into Orleans," "The Battle of Sedan," "The Germans in Versailles," and "The Entry of the German Army into Paris." The great success of the "Battle of Sedan," in panoramic form, induced Braun (who in 1902 held a professorship in Munich) to produce several other works of the same description. Among these are the "Battle of Mars la Tour" (1884), "Panorama of the German Colonies" (with Petersen, 1885), and the "Battle of Lützen" (1892). His elder brother, REINHOLD BRAUN (1821-84), animal and genre painter, was born at Altensteig, Württemberg, and studied painting and lithographing in Stuttgart and later in Munich. He is especially well known for representations of horses, the coloring and delicate execution of which earned for him the name of the "Swabian Wouwermann." His genre scenes of Swabian life are very popular and have often been reproduced in woodcuts and photographs. He is represented by several characteristic works in the museums of Leipzig, Munich, and Stuttgart.

BRAUNE, bra'ne, CHRISTIAN WILHELM (1831-92). A German anatomist. He was born in Leipzig and studied at the universities of Göttingen and Würzburg. In 1872 he became professor of topographical anatomy at the University of Leipzig. In his scientific investigations Braune devoted himself particularly to the mechanical physiological side of anatomy, particularly as regards the movements of the joints and the equilibrium of the body in their bearing upon the equipment of the infantry. He also introduced dissection of frozen corpses into the technique of anatomy. Among his numerous works are the following: *Die Doppelbildungen und angeborenen Geschwülste der Kreuzbein- und Kreuzbindergegend* (1862); *Topographisch-anatomischer Atlas, nach Durchschnitten an gefrorenen Kadavern* (1872); *Die Lage des Uterus und Fötus am Ende der Schwangerschaft nach Durchschnitten an gefrorenen Kadavern* (1873); *Das Venensystem des menschlichen Körpers* (1884-88). In collaboration with His, he edited, after 1870, the *Archiv für Anatomie und Entwicklungsgeschichte*. He was also instrumental in securing the publication of the musical works of Frederick the Great.

BRAUNE, THEODOR WILHELM (1850-). A German philologist, born in Grossschönig, Saxony. He graduated at the University of Leipzig and afterward served as professor of the German language and literature at the universities of Leipzig (1877), Giessen (1880), and Heidelberg (1888). His published works include: *Beiträge zur Geschichte der deutschen Sprache und Literatur* (1874-91); *Neudrucke deutscher Literaturwerke des 16ten und 17ten*

Jahrhunderts (1876), *Althochdeutsches Lesebuch* (1875, 6th ed, 1907), *Gothische Grammatik* (1880, 7th ed, 1909, Eng trans, 1883, from 2d ed.), *Althochdeutsche Grammatik* (1886, 4th ed, 1910) *Der Gang des Menschen* (Leipzig, 1898-1903), *Ueber die Einnahme der deutschen Aussprache* (Heidelberg, 1904), *Die Fabeln des Brucius Alferus* (Halle, 1892)

BRAUNITE, brou'it, a siliceous sesquioxide of manganese, which occurs associated with manganese deposits notably at Ilmenau, Thuringia, and Ilfeld in the Harz. It occurs in tetragonal, pyramidal crystals, black or steel gray in color, and with submetallic lustre

BRAUNSBURG, brouns'bérk (earlier *Brunsbérg*) A town of East Prussia, in the administrative district of Königsberg, about 35 miles southwest of the city of that name (Map Prussia, H 1) It is situated on the Passarge, 5 miles from its junction with the Frisches Haff. It contains a Catholic seminary, a gymnasium, and the Lyceum Hosianum founded by Bishop Hosius in 1568. The industries consist of a large number of manufactories, the principal articles being soap, leather, yeast, and felt ware, and a trade in grain and flax. It has regular steamship communication with Pillau and Königsberg. The town was founded about 1251 by the Teutonic Knights. It has belonged to Prussia since 1772, the date of the first partition of Poland. Pop. 1900, 12,497, 1910, 13,601

BRAURONTA A festival in honor of Artemis, celebrated at intervals of four years at Brauron, a village near Marathon, now called Vraoua. At the festival Attic girls between 5 and 10 years of age were consecrated at the sanctuary of Artemis. A part of the rite consisted in the imitation of the actions of bears by the girls. According to tradition, this rite originated in a plague sent upon the Athenians by Artemis in punishment for the killing of a tame bear which had torn a little girl in pieces because the girl had irritated it. To propitiate the goddess, the rite was instituted, and all Attic women were obliged to take part in it before they were permitted to marry. To Brauron Orestes (qv) and Iphigenia (qv) were supposed to have brought from Tauris the statue of the Tauric Artemis

BRAUWER, brou'ér, ADRIEN See BROWER

BRAVA'S, brá'vaz, KNIGHT. In Ariosto's poem, a name for Orlando Furioso, who was Marquis of Brava

BRAVI, brá'vé (It pl of *bravo*, brave). Originally the retainers of a noble house and the champions of its quarrels. Later the bravi were wont to offer their services to any one for money. The internal history of Italy for many centuries is replete with the actions of these men, who in time became nothing more than hired bandits and assassins. In a more favorable sense *bravo*, the singular of *bravi*, was applied to the dueling, love-making, sonnet-writing, and stabbing type of gentleman that flourished amid the lax morality of the Renaissance

BRAVO-MURILLO, brá'vó-mú-ré'lyé, JUAN GONZÁLEZ (1803-73) A Spanish statesman. He studied theology for a time, was afterward a lawyer in Seville, and then became the editor of the first law journal in Spain, the *Boletín de Jurisprudencia*, founded by him and Pacheco in Madrid in 1835. With others he also established later the conservative papers *El Porvenir* and *El Piloto*. In 1837, and again in 1839, he was a leading member of the Cortes, but was pro-

scribed after the Revolution of 1840 and took refuge in France. He returned in 1843 on the downfall of Espartero, was a member of the Ministry in 1847, and on the resignation of Narváez in 1851 formed a new cabinet, but resigned as Prime Minister in 1852, after having pursued a reactionary policy. The Revolution of 1854 caused him to leave Spain again, but he was recalled by Narváez in 1856 and afterward was intusured with important diplomatic missions. In 1868 he was again of the cabinet, but within the year followed the Queen when she was forced to flee to Bayonne

BRAVURA, bra-voo'ra (It bravery, spirit, dash) A term which, applied to a musical composition, means that the music is written in a dashing, brilliant style, full of ornamentation and colorature that put to a severe test the abilities of the performer. Such compositions are often written to display the power, volume, or flexibility of a voice or the digital facility, power, and endurance of an instrumental performer. In the early part of the nineteenth century the excessive liberties taken by singers in improvising trills and runs to exhibit their voices induced Rossini to write out the bravura passages in his works so as to insure them against disfigurement by tasteless singers. It was owing to these latter that bravura fell into discredit. That it can be united with true artistic merit, the works of Mozart, Beethoven, Weber, Mendelssohn, Chopin, and others give abundant proof

BRAWE, bra'vé, JOACHIM WILHELM, BARON VON (1738-58) A German dramatist, born in Weissenfels (Saxony). He studied at the University of Leipzig, where he associated with Lessing, Weiss, and E. von Kleist, and was appointed to the government board in Merseburg, but died before he had taken office. His *Der Freigeist*, a tragedy, was influenced by Lessing's *Miss Sarah Sampson*. His *Brutus*, with Lessing's *Kleopatra*, the first German dramas to be written in unrhymed iambic pentameter, gave evidence of unusual poetic talent. They were edited by Ramler and Lessing (Berlin, 1767). Consult Saer, "Brawe, der Schuler Lessings," in Ten Brink and Scherer, *Quellen und Forschungen zur Sprach und Kulturgeschichte der germanischen Völker*, vol. xxx (Strassburg, 1878)

BRAWLING (OE *braulan*, to quarrel, boast, biallan, to cry, make noise, Ger *bräulen*, Fr *brailleur*, to cry, shout) As a criminal offense, the creating of a disturbance in a consecrated building or inclosure. This was considered a heinous offense both by the ecclesiastical and the common law of England, "as being a very great indignity to the Divine Majesty, to whose worship and service such places were dedicated." By the Brawling Act of 1860 (23 and 24 Vict c 32, § 2), any person guilty of riotous, violent, or indecent behavior in a church, chapel, churchyard, or burial ground, is liable to a fine of not more than five pounds, or to imprisonment for not more than two months. In the United States similar acts are punishable, generally, as affrays or breaches of the peace. See AFFRAY, BREACH, and the authorities referred to under CRIMINAL LAW

BRAXTON, CASTER (1736-97) An American patriot, one of the signers of the Declaration of Independence. He was born in Newington, Va., of wealthy parents, and was educated at William and Mary College. From 1761 to

1771 he was a member of the House of Burgesses, and, as such, took an active part in all the disputes with the royal governors, and in 1765 strongly advocated the adoption of Patrick Henry's Stamp Act resolutions. He was a member, also, of the conventions which met in Williamsburg (August, 1774) and in Richmond (July, 1775), and served as a delegate to the Continental Congress from December, 1775, to Aug. 11, 1776, during which time (on August 2) he signed the Declaration of Independence. Afterward he was frequently elected to the House of Delegates and was twice a member of the Council of State. He was a representative of the "aristocratic party" in Virginia, and by his views with regard to the organization of a new government—notably those in his *Address to the Convention of Virginia on the Subject of Government* (1776)—gave considerable offense to the more radical members of the Patriot Party. Consult Sanderson, *Biography of the Signers of the Declaration of Independence* (5 vols., Philadelphia, 1829).

BRAX'Y, BRAK'SY, BRAX'ES, BRAX'TT, BRACKS, or BRAASOT (Scotch, origin unknown). Terms synonymously used to designate several different diseases in domestic animals. They are perhaps most correctly applied to a disease of sheep, which has also been called "the sickness" in some parts of Scotland, "Braasot" in Norway, and "Maladie subite du mouton" in France. This disease appears as an epizootic and is due to the action of a pathogenic organism, *Bacillus gastrimycolosis ovis*, which causes a severe inflammation, especially of the abomasum and duodenum. The braxy bacterium rapidly loses its virulence in cultures and does not develop in the presence of oxygen. Ingestion appears to be the common natural method of infection. The germs exist in the soil of infested localities and are taken into the stomach along with the fodder. The disease appears in the autumn, becomes most prevalent in winter, and usually disappears in spring, being but rarely seen in summer. Sheep from a few months (weaned lambs) up to two years of age are most susceptible to its attacks. The animal in full health suddenly ceases to eat, has a staring look, is peculiarly excitable, and separates itself from the flock. The head is lifted high, the breathing becomes labored, the countenance appears anxious, and the animal loses the power of its limbs. It totters, falls over, is seized with convulsions, and dies within five or six hours, and often within an hour from the first symptom of the disease. Tumors are frequently developed on the neck and shoulders. If the sheep's throat is cut before it dies, the absence of any peculiar appearances within the body is very remarkable; the flesh appears of a dark-red color, and the veins are charged with dark blood, but, on the whole, the body of the sheep looks so well that the mountain shepherd cuts it up to make "braxy mutton," which has a fetid odor. If the sheep is allowed to die of itself, the body soon swells, putrefies, and is rendered useless. It is doubtful whether the meat should ever be eaten. A method of vaccination in which peritoneal fluid from braxy cases is used gives good results, the mortality from braxy following its use never exceeding 1 per cent, even in the most severely affected districts. Shelter during severe winter weather is insisted on by shepherds as essential to prevent the malady. The prognosis is very un-

favorable. In Ireland the disease is invariably fatal.

BRAY. A maritime town of Ireland, situated partly in the county of Dublin, partly in that of Wicklow, at the mouth of the Bray, 13 miles southeast of Dublin (Map: Ireland, E 3). From a small fishing village Bray has developed into a popular watering place, owing to the beauty of its situation. It has a long esplanade, good hotels, Turkish baths, electric lighting, etc., and is sometimes called the "Irish Brighton." Pop., 1901, 7424.

BRAY, MRS. ANNA ELIZA KEMPE (STOTHARD) (1790-1883). An English novelist, born in London. She published a considerable number of works of historical fiction and volumes of travel, including *The Borders of the Tamar and the Tavy* (1836), *Trelawny of Trelawne* (1837), and *A Peep at the Pixies* (1854). After a long silence she issued in 1870 three French historical novels, *The Good St. Louis and his Times*, *The Revolt of the Protestants of the Cevennes*, and *Joan of Arc*. The fiction was collected in a 12-volume edition in 1884 and in the same year appeared her *Autobiography*, ed. by Kempe (London, 1884).

BRAY, FRANK CHAPIN (1866-). An American editor and educator, born in Salineville, Ohio. He was a printer's apprentice, worked his way through college as a printer and reporter, graduated at Wesleyan University in 1890, became city editor of the Middletown (Conn.) *Herald* in 1891, and was managing editor of the *Morning Despatch* of Erie, Pa., in 1892-04. For six years he edited a department called "Topics of the Day" in the *Literary Digest*, and in 1899 became editor of *The Chautauquan*, the organ of the Chautauqua Literary and Scientific Circle. In 1902 he was made editor in chief and in 1906 editor manager of the Chautauqua Press, which publishes the magazine just mentioned and the study courses of the Chautauqua circle. He wrote *A Reading Journey through Chautauqua* (1905).

BRAY, bñ, OTTO CAMILLUS HUGO, COUNT OF BRAY-STEINBURG (1807-99). A Bavarian statesman. He was born in Berlin and after completing his studies in that city entered the diplomatic service of Bavaria. At first Counselor of Legation at St. Petersburg and at Paris, he later successively became Ambassador to Greece and Russia, Minister of Foreign Affairs (1846 and 1848), again Ambassador to Russia and Ambassador to Austria. In 1870 he succeeded Prince Hohenlohe as Minister of Foreign Affairs, in which capacity he negotiated the union between Prussia and Bavaria in 1870 and the admission of the latter into the German Empire. He retired from political life in 1896.

BRAY, SIR REGINALD (died 1503). An English statesman and architect, a favorite of Henry VII., from whom he received many royal benefits. At the coronation of Henry VII. Bray was made Knight of the Bath and later he became a Knight of the Garter. He was awarded a grant of the constableness of Oakham Castle in Rutland, was appointed to serve with Lord Fitzwalter as chief justice of all forests south of Trent, became High Treasurer and Chancellor of the Duchy of Lancaster, and served a term in Parliament. In October, 1494, he was appointed high steward of the University of Oxford and is believed to have held the same office in the University of Cambridge. For his bravery at the battle of Blackheath, June, 1497, he was made

a knight banneret and was given a large estate. One of the leading architects of his time, he designed St Mary's Tower at Taunton, and the decorative work of the interior of St George's Chapel at Windsor. His masterwork is the chapel of Henry VII at the east end of Westminster Abbey, if indeed this attribution be correct. The probability is that it was designed by Robert Vertue, and erected by William Bolton as Master of Works, and that Bray's share in its design was subordinate to Vertue's and confined to the decorative detail.

BRAY, THOMAS (1656-1730). An English prelate and philanthropist, born at Marton (Shropshire). He graduated at Oxford in 1678 and was appointed to the vicarage of Over-Whitacre and the rectory of Sheldon. In 1698 he founded the Society for Promoting Christian Knowledge and in 1700 organized the Anglican church in Maryland. He obtained the passage by the Provincial Assembly of the Act of Religion, which in 1701 received royal sanction. A charter was acquired by him in 1701 for the Society for the Propagation of the Gospel in Foreign Parts. In 1706 he became rector of St Botolph's, Aldgate. He projected and extended a system of parochial lending libraries to be established in every deanery and in 1723 founded for the continuance of his work the society known as the "Associates of Dr Bray," which still exists and publishes annual reports. He was also interested in other benevolent works. He published *Upon the Preliminary Questions and Answers* (1696, vol. 1 of *Lectures upon the Church Catechism*, incomplete), *An Essay Toward Promoting All Necessary and Useful Knowledge* (1697), *Apostolick Charity* (1698), *Directorium Missionarium* (1726). A selection of his writings relating to Maryland, with a memoir by Rawlinson, was published in 1901 by the Maryland Historical Society.

BRAYMAN, MASON (1813-95). An American lawyer and soldier, born in Buffalo, N. Y. He was early apprenticed to a printer, was editor of the *Buffalo Bulletin* in 1834-35, and was admitted to the bar in 1836. After 1837 he lived successively at Monroe, Mich., Louisville, Ky. (where he edited the *Advertiser*), and Springfield, Ill. In 1843, as a special commissioner for the State of Illinois, he was charged with adjusting the difficulties arising from the settling of the Mormons at Nauvoo (qv) and was also instrumental in securing the removal of the Mormons from the State in 1844. He revised the Illinois Statutes under authority of the Legislature in 1844-45 and from 1851 to 1855 acted as attorney for the Illinois Central Railroad. Having entered the Federal army as major of volunteers on the outbreak of the Civil War in 1861, he was a chief of staff and assistant adjutant general to General McClelland in 1862, was raised to the rank of brigadier general of volunteers in September, 1862, repelled Van Dorn's attack on Bolivar, Tenn., was in command at Natchez in 1864-65, and at the close of the war was brevetted major general. He subsequently took an active interest in the organization and management of railroads, was editor of the *Illinois State Journal* in 1872-73, and served as Territorial Governor of Idaho from 1876 to 1881.

BRAZEN AGE, THE. One of a group of four plays by Thomas Heywood. The group, known as *The Four Ages*, consists of *The Golden Age* (1611), *The Silver Age* (1612), *The Brazen*

Age (1613), *The Iron Age* (printed 1632). The plays deal with the most famous of the Greek myths and are largely founded on Ovid's *Metamorphoses*. The author's treatment of the subject does not rise entirely above the bulesque.

BRAZEN SEA. A large vessel of copper, 5 cubits high and 30 (or, according to the Septuagint, 33) in circumference, 10 cubits in diameter, placed by Solomon in the priest's court for the use of servitors. It rested on 12 oxen, 3 placed on each side, with heads facing outward. The basin is said to have held about 2000 measures (baths) of water (1 Kings vii 23-26), according to 2 Chron iv 6, it was used by the priests for ablutions prior to approaching the altar, but it seems likely that it originally had a symbolical significance rather than a practical use. In the Babylonian religion, as in Semitic cults in general, the bull is a mythological emblem. Aliaz moved the brazen sea from the base of oxen and placed it on a stone base (2 Kings xvi 17). The sea was finally broken by the Chaldeans and the copper carried to Babylon (2 Kings xxv 18).

BRAZEN SERPENT. Moses is said to have made a serpent of brass and erected it on a staff before the people, so that whosoever looked upon it should be healed (Num xxi 9). In the time of Hezekiah the brazen serpent was looked upon as a sort of divinity and incense was burned to it. In his reform it was broken to pieces together with other insignia of foreign worship (2 Kings xviii 4). Many scholars regard the story in Num xxi 9 as an account of the origin of this *Nehushtan*, or 'brazen serpent'. Among the Egyptians the uræus serpent was regarded as especially sacred and adorned the entrances to their temples. In the Assyrian and Babylonian sanctuaries serpent images stood as guardians at the doors. The serpent was also looked upon by the Phœnicians as a god of healing.

BRAZIL', *Portug. pron* brá-zil' (from the color of its dyewoods, *brasa*, Portug. *brasa*, a live coal), UNITED STATES OF. The largest country in South America, and one of the most extensive political subdivisions of the world, including the central and eastern portions of the continent. It is embraced, approximately, between lat 5° N and 34° S and between long 35° and 74° W, its greatest length from north to south is about 2660 miles and from east to west 2700 miles, the total area is estimated at 3,301,350 square miles. Its limits on the northeast and southeast are the Atlantic Ocean, while the remaining portion of the northern boundary is formed by the Guianas, Venezuela, and Colombia, on the west, southwest, and south it touches Peru, Bolivia, Paraguay, Argentina, and Uruguay. It lies entirely to the east of the Great Andean system.

Northern and western Brazil is occupied by the basin of the Amazon, and while the political boundary extends to the mountains and highlands on the north, yet almost the whole of this section is a great plain, the so-called *selvas*, in which the altitude does not exceed 1000 feet and the greater part is below 500 feet. The southern and eastern part of Brazil is plateau-like in character, rising above 2000 feet in altitude, and much of it above 4000 feet, it is broken by the valleys of the source streams of the Paraná and of the upper Uruguay in the south, of the Tocantins and Araguaia in the north, and the São Francisco in the central and

eastern parts. This tableland, which is best designated the Brazilian Highlands, is geologically the oldest part of South America. It was elevated bodily, with little, if any, distortion, and the present configuration of the surface is due to differential erosion, by which the harder and more resistant rocks have been preserved in the mountain ranges. It results from this mode of origin that the ranges are irregular in distribution and trend. They may, however, be grouped in three systems, the most important of which is the Serra do Mar, which forms the southeastern slope of the plateau to the narrow strip of coast along the Atlantic. In this system, west of Rio de Janeiro, is the highest peak in Brazil, Itatiaia, 8900 feet in height. The system bears many different names in different parts, as Serra Geral, Serra da Mantiqueira, and Serra dos Amores. Connecting with this range near Rio de Janeiro and stretching northward between the São Francisco and the streams flowing directly to the coast, is the Serra Central, while a third range trends northwestward, separating the heads of the São Francisco and Tocantins from those of the Parana. Minor ranges and ridges separate the tributaries of these rivers from one another. West of this great plateau of eastern Brazil a highland stretches across to the Andes, dividing the waters of the Amazon from those flowing southward to the Rio de la Plata. On the north, the Tumuchumac and Acaí mountains separate Brazil from the Guianas, and the Serra Pacaraima separates it from Venezuela. The Atlantic coast line has a length of about 4000 miles. North of Cape St. Roque it is comparatively low, and the slope towards the sea is gradual, but south of the cape the coast line gradually becomes more elevated, the slope of the sea is steeper, and at the extreme south very abrupt. The north coast is but little broken and thus offers but few fine harbors and not many islands, but at the south good harbors are not wanting.

Hydrography. The rivers of Brazil possess a degree of importance greater than most of the other rivers of the world, since they form the chief, and in some cases the only, highways of travel and commerce through a region of great natural resources. Owing to the copious rainfall and the mild climate, navigation of most of them is possible throughout the year, in spite of their great fluctuations in volume from the wet to the dry season. More than two-thirds of Brazil, 2,235,000 square miles, is drained by the Amazon and Tocantins, about a fourth by the Paraguay-Paraná system, while the remainder is drained by the São Francisco and smaller streams. The Amazon with its great branches, the Negro, Japurá, and Içá on the north, the Javary, Jurua, Purus, Madeira, Tapajoz, and Xingó on the south, with the Tocantins, which joins it in its delta, affords a system of internal navigation comparable only to that of the Mississippi. The length of the main river from the Peruvian boundary to its mouth is about 2500 miles, practically all of which is navigable. The total length of the Amazon and its main branches within Brazil is estimated at 10,000 miles, of which 13,000 miles are navigable. The navigable stretch is much longer on the upper than on the lower branches, as the latter head in the plateaus of Guiana and southeast Brazil, and are interrupted by rapids and falls, especially where leaving the plateaus. Such is the

case also with the São Francisco, where navigation is interrupted by the falls of Paulo Afonso, only 60 miles above the river's mouth. The Negro, a large northern branch of the Amazon, is connected through the Casiquiare with the Orinoco. See also AMAZON, TOCANTINS, etc.

Unexplored Regions. The largest unexplored areas of South America are in Brazil among the tropical forests of the Amazon basin. The greater portion of the basin, and especially the southern part, is covered by virgin forest, with only here and there a campo or plain of comparatively small extent. The dense undergrowth renders these forests almost impenetrable except along the navigable streams. Until recently explorers have not traveled inland away from the banks of the great north and south affluents of the Amazon, thus most of the forest was unknown except along the water highways. Two inducements—the quest for rubber and ethnological investigation—have, since 1900, resulted in many journeys along affluents of the Amazon tributaries and the penetration of the country on either side. The unexplored areas, though still embracing hundreds of thousands of square miles, are being reduced every year by the invasion of rubber hunters, including men of scientific training, such as Kahler, Ule, and others, who are spending years in studying the distribution and extent of the rubber resources. This work is stimulated by the fact that there are no rubber forests on the Amazon as we should speak of oak or pine forests, but rubber trees are scattered among other kinds of timber forming only a small percentage of the trees. An area must be well explored in order to ascertain its rubber-yielding value. Ethnological research has in recent years especially contributed to geographical discovery in the northern part of the Amazon basin. The four journeys of Dr. Koch-Grünberg (1903-05) for the study of Indian tribes resulted, for example, in the mapping of the unknown headwaters of the Rio Negro. The largest unknown areas are now in the southern part of the basin between the Tocantins and the Madeira rivers.

Climate. Brazil lies almost entirely within the tropics, the region of the trade winds, and is dependent upon the latter for its rainfall and upon the Atlantic as the source of moisture. Wet and dry seasons alternate, as the movement of the trades follows the sun from north to south, the effects being modified by the direction of the coasts and the relief of the surface. In the greater part of the country the climate is remarkably constant, with a fairly uniform temperature throughout the year and a heavy rainfall. In the great Amazon valley, which is low and moist, densely forested, and subjected at all times to the sweep of the trades, the temperature averages about 90°. The annual range is about 40°. Moist winds afford a copious rainfall, ranging commonly from 75 to 100 inches and increasing to much greater amounts at the foothills of the Andes, where the air currents are forced upward into colder regions. It is believed that in some parts of the valley of the Amazon the rainfall is fully 300-400 inches. While the wet and dry seasons are not strongly marked, most of the rain falls between January and June. On the coast of the plateau region of southeastern Brazil there is a greater range of temperature with the seasons, and a more strongly marked seasonal rainfall, the greater part of the annual precipitation coming

in the summer, when the sun is south of the equator, and the trades have moved south with it. In the interior of this plateau region the seasonal distribution of the rain is still found, but the amount is much less than on the coast, indeed, in some regions, as between the São Francisco and the Paraná, the rainfall is deficient in amount.

Flora. The flora of Brazil may be divided roughly into three zones—that of the lowlands of the Amazon basin, that of the southeastern plateau, and that of the broad divide separating tributaries of the Amazon from those of the Paraná-Paraguay system. Vegetation on the lowlands of the Amazon is of the most luxuriant character. Along the coast mangroves, mangoes, coconuts, dwarf palms, and the Brazilwood are noticeable. Most of the Amazon basin is a vast forest stretching from the foot of the Andes to the sea, with a great variety of palms and hard woods and a number of rubber trees including 12 varieties of *Hevea*. *Hevea brasiliensis* yields the famous Pará rubber. Among the indigenous or widely cultivated fruits are the pineapple, fig, custard apple, mango, banana, guava, grape, and orange. European grapes, olives, and watermelons of fine flavor are cultivated. On the southeast coast, within the tropics, where the rainfall is abundant, there is a similar profusion of vegetation, succeeded southward by plants of a more temperate climate. Inland, as the rainfall diminishes, upon the plateau, the vegetation becomes less abundant and changes in character to open forests of smaller trees, with palms, ferns, and cacti. This is the caatinga country.

Fauna. The animal life of Brazil is extremely varied and differs in many important respects from that of the northern continent and the Old World. Of larger animals, there are the puma, jaguar, ocelot, and several members of the dog family. The capibara, peccaries, and tapirs are abundant, also ant-eaters, sloths, opossums, and armadillos. Deer are plentiful in the more open country of the south, and monkeys of many species abound in the silvas. There is a great variety of birds, which are characterized by the brilliancy of their plumage and their dissimilarity to the birds of other countries. Snakes are abundant, several species, including the rattlesnake and jararaca, being venomous; the boas reach an enormous size. The inland waters swarm with fish and turtles, and certain cetaceans ascend far up the Amazon.

Geology. The southeast table-land is in the main composed of crystalline rocks, including granite, gneiss, and schist of Archean age. These rocks also extend westward from the states of Minas Geraes and São Paulo into the interior of Matto Grosso, forming the divide between the Amazon and the Paraná-Paraguay systems. A second Archean area is found in the highlands bordering the Guianas, near the northern boundary, and there are smaller detached areas in the middle portions of the Tocantins and Xingú valleys. Paleozoic strata occupy the flanks of the Archean, while Cretaceous and Triassic beds cover a large portion of the plain of central Brazil. The Tertiary and Quaternary formations are developed along the Amazon valley and the coastal regions. The Archean rocks are the source of the famous diamond and gold deposits of Minas Geraes, which have been very productive in the past and are still the basis of an important mining indus-

try. The manganese ore deposits in the same state are perhaps the most extensive in the world.

Mineral Resources. Brazil is one of the richest mineral-bearing countries in the world; but scarcity of population and capital, together with restrictive mining legislation, are in the way of an active development of the country's possibilities. It is estimated that no less than \$800,000,000 worth of gold had been exported from Brazil prior to 1820, one-half of which came from the state of Minas Geraes, which is to Brazil more than California and Pennsylvania together are to the United States. Formerly there were extensive surface diggings of gold and diamonds, but they have been mostly exhausted. At present gold mining is carried on to a limited extent in Minas Geraes, mostly with the aid of British capital. The production reached \$2,500,000 in 1900, \$2,043,500 in 1904, and \$1,900,000 in 1910. Minas and Bahia yield about 40,000 carats of diamonds a year; the exports in 1911 were valued at only \$19,918 milreis paper (about \$100,000). The production since 1723 is valued at \$100,000,000.

Iron, lead, copper, zinc, manganese, and quicksilver also abound, but the mining of these metals is impeded by lack of cheap fuel and labor. Several attempts were made in recent years, not only to mine iron and other ores, but to smelt them and even convert them into the finer manufactured products; but most of the smelting works, blast furnaces, and rolling mills had to shut down on account of the difficulties mentioned. Some bituminous coal is mined in Rio Grande do Sul and Santa Catharina, and lignite in some of the other states; but although the coal beds of Brazil extend from São Paulo in the north down to Rio Grande do Sul, being quite thick in the south, they are of an inferior quality, and the coal requires considerable washing to become useful. Marble and other valuable building stones abound. Rock salt, phosphate of lime, kaolin, and hot mineral springs also occur.

Agriculture. Only a small portion of the surface of Brazil suited to agriculture is under cultivation. This is in great measure due to the fact that Brazil is a country of relatively recent settlement. Even so, the agricultural population is small, as a rule, and the farms and plantations are tilled in a very primitive manner. In many parts the gathering of forest products is preferred. The most profitable crops—coffee and sugar—naturally have the largest areas devoted to them, tobacco and cotton coming next. The coffee plant is most extensively grown in the states of Rio de Janeiro, Minas Geraes, and São Paulo. The industry has suffered in recent years from overproduction. The annual yield increased from 4,600,000 bags (of 132 pounds each) in 1890 to 11,000,000 in 1900, and 12,000,000 bags in 1912. Vigorous efforts have been made by the federal government and by the government of São Paulo to maintain and advance the price of coffee,—by the imposition of an additional tax on exports over a certain amount, by the purchase of immense quantities of coffee, which were thus removed from competition in the world's markets, and by a propaganda to encourage the world's consumption. Nearly all the coffee used in the United States comes from Brazil. The Atlantic states yield the sugar supply, especially Bahia and Pernambuco. Cotton of excellent quality is produced in every state. The tobacco is inferior to that of the West Indies. The

greater part of the tobacco exported is grown in Bahia. Maize and rice are among the leading products of Minas Geraes and São Paulo, but not enough is raised for home consumption. The small grains do not flourish. Among the more common food products are sweet potatoes, yams, beans, and the farina prepared from the root of the manioc or cassava (qv). Cacao is grown in northeastern Brazil, and the leaves of the holly, or ilex, which yields the maté (qv), or Paraguay tea, are gathered in the extreme southern States, especially in Paraná. Pumpkins, squashes, cabbages, okra, tomatoes, onions, cucumbers, and other vegetables are raised. The raising of cattle and the breeding of horses give occupation to many in the southern state of Rio Grande do Sul. Although Brazil has many kinds of durable woods, timber for making railroad cars is imported from India. Large quantities of salt fish are brought from the United States, when Brazil might easily supply her needs by improving her own fisheries.

Manufactures. Long occupying a subordinate place as compared with agriculture, mining, and the collecting of forest products, manufactures are becoming more important. They are taking the natural course of development, those industries thriving most which are devoted to the manufacture of goods from the natural agricultural and mining products of the country. Thus the textile industry is the most important, cotton spinning and weaving taking first rank, followed by woolen manufactures. In 1910 there were 194 cotton mills with 761,816 spindles and 27,958 looms, employing about 40,000 operatives and producing annually over 20,000,000 yards of cloth. Most of the mills are in Rio de Janeiro, Minas Geraes, and São Paulo. The same is true of the location of the woolen mills, whose number, however, is small. Sugar refining is the next industry in importance. In the states of Bahia and Pernambuco and elsewhere the refining of sugar is extensively carried on by the diffusion process, and in remote districts by somewhat primitive methods. Several kinds of rum are distilled in the sugar districts, and cigar making is an important industry. The smelting of metals, the manufacture of steam engines and agricultural tools, the tanning of leather and working of hides, and the manufacture of salt, straw hats, soap, and candles employ many hands, and within recent years the list of artificial products has been lengthened by the addition of paper, calicoes, powder and dynamite, glass, wines, beer, cottonseed oil, castor oil, wax matches, and sulphuric acid. Shipbuilding is carried on in several ports.

Transportation and Communication. The first railway in Brazil was opened to traffic in 1851. It was only 9 miles long, and connected Porto de Mauá, on Rio de Janeiro Bay, with Ruiz de Serra. The line was a purely private undertaking. In 1855 the first private line built under a government guarantee was constructed, the same year having witnessed the opening of the first government railway. Since then the government has taken an active part in railway development.

The two main railway systems radiate from Rio Grande do Sul and Rio de Janeiro, the latter extending especially into the state of São Paulo. These two systems have recently been connected, thereby allowing continuous communication by rail between Rio de Janeiro and Montevideo in Uruguay. A third railway

system has Bahia and Pernambuco as centres. The total length of railways has been as follows: 1860, 109 miles, 1870, 448, 1880, 2120, 1890, 5995, 1900, 9102, at the end of 1911, 13,848, and 2387 miles more under construction. The length of railway owned and operated by the government at the end of 1911 was approximately 2033 miles, leased by the government to companies, about 4750 miles, concessions to companies with interest guaranteed, about 1875 miles, concessions without guarantee of interest, about 1200 miles, state (as distinguished from federal) concessions, over 3950 miles. The total mileage in operation at the end of 1912 was 14,338. Telegraphs in 1909: lines, 36,109 miles, wire, 73,124, offices, 2070.

Shipping. As the railway system is very little developed, Brazil is chiefly dependent upon its coastal waters and rivers as highways for its domestic trade. The shipping trade is therefore unusually prominent, and as far as it relates to commerce between different parts of the republic, it is confined to vessels flying the Brazilian flag, as the government excludes all foreign vessels from the coasting and river trade. Brazil's merchant marine numbered, in 1911, 238 steamers and 290 sailing vessels. Nearly four-tenths of the total tonnage of vessels entering Brazilian ports is domestic shipping. In 1905 the number of vessels entered at all Brazilian ports was 17,072, with a total tonnage of 12,927,000, and the number of vessels cleared was 17,064, with a tonnage of 12,926,000. The chief port is Rio de Janeiro, the New York of Brazil, receiving two-fifths of Brazil's imports and shipping one-sixth of its exports. Other important centres of foreign commerce are Bahia, Pernambuco, Ceará, Paráhyba, in the north, and Santos, Paranaguá, Desterro, Porto Alegre, and Rio Grande do Sul, in the south. In 1867 the Amazon was opened to all nations. Twenty-three steamship lines are subsidized by the government, including two from Santos to Hamburg and Genoa. Of six lines between Brazil and the United States, four are British and one is German.

Commerce. Brazil has a larger foreign commerce than any other of the South American republics. In 1861 the exports from Brazil were valued at \$20,000,000, in 1890 they rose to \$140,000,000, and in 1912 reached the sum of \$363,535,000. The imports amounted to \$115,000,000 in 1890 and \$308,631,000 in 1912. Coffee is the staple article of commerce, meaning more to the exports and to the prosperity of Brazil than wheat does to the United States. It constitutes about 60 per cent of the total exports of the country in value. More than two-thirds of the coffee goes to the United States and the remainder to Europe. Rubber is next in importance, the United States taking nearly two-thirds of the supply. Then come cotton, cottonseed, hides, tobacco, cacao, maté (or Paraguay tea), dye and cabinet woods, etc.

The imports consist of all kinds of manufactured goods, cotton and woolen fabrics, machinery, ironware, coal, petroleum, and food stuffs, including flour, corn, jerked beef, pork, butter, lard, olive oil, wines, etc. In 1910 Great Britain controlled nearly one-fourth of the import trade, and the imports of the United States and Germany were together worth the same as the goods bought from Great Britain. The value of the imports from the leading countries was as follows in 1910: Great Britain, \$87,000,000, Germany, \$37,500,000, United States, \$30,250,-

000; France, \$22,270,000; Argentine, \$20,130,000; Belgium, \$10,650,000. Wheat flour and kerosene were the most important imports from the United States. Owing chiefly to the growing consumption of Para rubber in the United States as well as to the enormous demand for coffee, this country is gradually increasing its imports from Brazil and reached in the calendar year 1911 the high figure of \$123,000,000, while in 1909 it was still higher, having amounted to \$124,000,000. Considerable attention is now centred in the cultivation of rubber, and the success of these experiments will tend to augment the export trade.

Banking. The first bank established in Brazil, the Banco do Brasil, was founded in 1808. Modern banking dates from 1853, when the new Banco do Brasil was established with a capital of 33,000,000 milreis as a bank of issue. In 1890 three more banks of issue were established, the "regional" banks for north, central, and southern Brazil, with a total capital of 450,000,000 milreis, which was to be invested in 5 per cent government bonds. The banks were given other privileges, the most important of which was the exemption from import duties of all goods brought in by them. This secured for them an absolute commercial monopoly, which naturally led to great dissatisfaction among the business interests. In the meantime the issue of paper money by the three banks, the national bank, and a number of other banks, which had also been authorized to issue paper money, swelled the total amount of it in circulation to over 700,000,000 milreis, resulting in the usual disastrous consequences of inflation. More than 100,000,000 milreis of paper money was destroyed by the government in 1900. In 1905 the Bank of Brazil was reorganized.

Government. Brazil is a federal republic, comprising 20 states, a Federal District, and a territory (Acré) under a constitution adopted Feb. 24, 1891. The legislative power is vested in the president of the republic and a national Congress, consisting of a Senate and a Chamber of Deputies. The Senate is composed of three members from each state and from the Federal District, elected directly by the people for nine years, one-third of the number being renewed every three years. The Chamber of Deputies consists of 212 deputies elected by popular vote for three years upon the basis of one representative to every 70,000 of the population; no state, however, may have less than four representatives in the Chamber. The franchise is granted to all male citizens above the age of 21—with the exception of beggars, illiterates, soldiers actually serving, and members of religious associations. The executive authority is exercised by a president elected by direct popular vote for four years. He is assisted by a cabinet of seven ministers, who preside over the following departments; Foreign Affairs; Interior and Justice; Finance; War; Navy; Communications; and Agriculture, Commerce, and Industry. They are not responsible to Congress nor can they participate in the debates of either chamber, but they may appear in their official capacity before the congressional committees. The president possesses the veto power on legislation, but his veto may be overruled by a two-thirds vote of both chambers. The judicial power is vested in a federal supreme court consisting of 15 members appointed for life by the president with the approval of the Senate.

The constitution of Brazil was modeled after that of the United States, but differs from it in the complete autonomy which it leaves to the individual states, an autonomy amounting almost to decentralization. The states are governed by their own legislatures and governors and possess their own judicial systems. The federal government may intervene in local affairs only for the purpose of repelling foreign invasion or of preserving a republican form of government, or of enforcing the execution of federal laws. The public domains within the boundaries of any state are the possession of that state and under its control. A state may subdivide its territory at pleasure or consolidate with another state. Though the control of foreign affairs is delegated to the federal government, single states have frequently sent abroad representatives, endowed with all the powers of fully accredited plenipotentiaries, for the purpose of negotiating important commercial treaties and dispatching public business. In general there is a disposition on the part of the states to reduce the federal authority to a minimum.

The states are divided into municipalities whose affairs are controlled by a council and a prefect. The term "municipality" does not bear the usual meaning of a civic corporation, but denotes rather a district, or territorial division. In Rio de Janeiro the municipal head is appointed by the president of the republic.

Justice is administered in the first instance by justices of the peace (elected by the municipalities) in civil disputes and by the commissioner of police in criminal cases. Appeals lie to courts of second instance, which are composed of trained jurists, and from them to the courts of appeal, of which there is one in the capital of each state. The civil code is based upon Roman law.

For national coat of arms see Colored Plate accompanying HERALDRY; and for colors see Colored Plate of FLAGS.

Army. The reorganization of the army under the law of January, 1908, was completed in 1912, the peace strength of all arms totaling about 32,000. Military service is obligatory between the ages of 21 and 45—two years with the colors, seven in the reserve, seven in the territorial army, four in the national guard, and four in its reserve. Men in the reserve are called up for four weeks' annual training besides monthly rifle practice; those in the territorial army have an annual training of two to four weeks. The standing army includes: 15 regiments of infantry, each of 3 battalions; 12 battalions of rifles; 15 machine-gun companies; 9 regiments of cavalry, each of 4 squadrons, and 5 regiments, of 2 squadrons; 45 4-gun batteries; 5 6-gun howitzer batteries; 9 4-gun horse batteries; 6 4-gun mountain batteries; siege artillery; and engineering and transport troops. The country is divided into 13 military districts. The principal war arsenal is in Rio de Janeiro. The infantry rifle is a modified Mauser.

Navy. The navy includes: two dreadnoughts (*Minas Geraes* and *São Paulo*) of about 19,250 tons each, laid down in 1907; one old battleship (*Riachuelo*), 5700 tons; two armored coast guards (*Deodoro* and *Floriano*, laid down in 1898), aggregating 6320 tons; two scout cruisers (*Rio Grande* and *Bahia*, laid down in 1907), aggregating 6200 tons; two monitors, 940; one old

protected cruiser (*Barroso*), 3450, two second-class cruisers, 5840, three torpedo cruisers, 3090, 10 modern destroyers, 6500, in addition, various old torpedo boats and gunboats, transports, etc. A third dreadnought, the *Rio de Janeiro*, 27,500 tons, was laid down at Elswick in September, 1911, and launched in January, 1913, but in September of the latter year the Minister of Marine announced that the vessel was not in harmony with the organization of the fleet and that the government had decided to sell it. The principal naval arsenal is at Rio de Janeiro, here also are dry docks and, on an island in the bay, the naval school.

Weights and Measures. The metric system has been in vogue since 1862. The gold milreis is worth 54 6 cents, the paper milreis fluctuates between 31 and 35 cents.

Finance. Brazil, like some of the other South American republics, has suffered the results of an increasing expenditure over revenue and a depreciating currency. Reckless extravagance or unscrupulous handling of public funds by the parties in power, a too liberal use of the printing press in turning out paper money, and a general disregard of the simplest rules of public finance—all combined to create a financial condition verging on bankruptcy. The first example of extravagance beyond income and of shiftlessness in management of public finance was given early in the nineteenth century by King John VI, who fled with his court to Brazil after his overthrow in Portugal. In the course of time matters became somewhat improved under the monarchy, but the inauguration of the republic brought about a new regime of recklessness fanned by party feuds and political upheavals. It must also be added, in justice to the republic, that the enormous debts piled up as a result of the costly wars carried on under the monarchy left no small burden for the former to shoulder. However, the expenditures were allowed to increase beyond the revenue from year to year, and the deficits were covered by fresh loans. The providing of political offices for the members of the party in power, coupled with unreasonable additions to their salaries and excessive prices paid by the government for all kinds of supplies, was largely responsible for the great increase of expenditure, and, as the revenue meanwhile continued to fall behind, the national debt rapidly increased. In 1898 the government, unable to meet its obliga-

tions, negotiated with the London house of Rothschild a new debt, limited to £10,000,000. This loan is of great importance for the possibilities, embodied in its terms, of a permanent improvement in the financial conditions of Brazil. According to these conditions the government was to retire an amount of paper money equal to the new debt. A new sinking fund for the ultimate retirement of the bonded debt was provided for. This fund, to be begun in 1911, is to be formed from yearly deposits each equal to one-half per cent of the existing debt. The effect of the new provisions was soon apparent. The total amount of paper money in circulation, which had swollen from 186,000,000 milreis in 1889 to 702,000,000 in 1897, was reduced to about 674,400,000 in 1904 and to 612,510,626 at the end of 1911. The budget for 1912 showed estimated revenue of 92,195,610 milreis gold and 512,627,500 paper and estimated expenditure of 59,248,045 gold and 449,952,452 paper. Public debt, Dec. 31, 1911, foreign, £82,003,120 and 300,000,000 francs, internal, 620,525,600 milreis, floating, 256,546,647 milreis, paper money, 612,519,626.

The chief sources of revenue under the new regime are import duties, which furnish one-half the total revenue, next in importance are excise, railways, stamps, posts, and telegraphs.

Population. Previous to 1872, when the first full census was taken, the estimates were based upon the official returns of 1817 and 1818. In 1850 the population was supposed to be about 7,000,000 and, in 1860, 8,000,000. In 1912 the estimated population was 25,000,000.

The population of Brazil is the largest of any country in the Western Hemisphere except the United States. The average density of 62 persons to the square mile is, however, far behind that of some of the Spanish-American countries, Mexico having 208, Chile, 130, and Colombia, 104. As in nearly all countries having a considerable immigration, the number of males is in excess of females, the 1900 census showed 8,825,636 males, 8,492,920 females, total, 17,318,556. Less than one-half of the people were whites, one-third were half-breeds, one-seventh negroes, and less than one-tenth Indians, nearly one-half of whom were practically savages. A considerable proportion of the so-called whites are people of mixed Caucasian, Indian, and negro origin. As shown by the table, several of the larger states of Brazil are

STATE	Area in square miles	Population			Density of population
		1890	1900	1908	
Acre Territory	73,750			65,000	0.8
Alagoas	10,230	511,440	640,273	786,600	76.7

Total	3,301,350	14,333,915	17,371,069	20,515,000	6.2

almost devoid of population, the bulk of the people living along the coast.

Immigration. As is the case with all new countries Brazil needed immigrants to develop her resources. Nothing is more natural, therefore, than that the Brazilian government should try to attract Europeans by offering the immigrants abundant land for colonization purposes. The immigration laws of Brazil, like those of Argentina, were drafted solely with that end in view, but have not been carried out with the persistency or ability which has marked the policy of the Argentinians and therefore have not been crowned with the same degree of success. From the earliest time most of the immigrants came from Spain, Portugal, and Italy. The German immigration which began in 1825 soon reached considerable proportions under the fostering care of the Hamburg "Kolonisationsverein," so that by the end of the seventies there were from 150,000 to 200,000 Germans in the country. These people were attracted to the southern states—Rio Grande do Sul, Santa Catharina, and São Paulo—where the government offered them, in addition to free transportation from Europe to the place of destination, from 60 to 125 acres of land per family and furnished provisions, implements, and seeds until the time of the first crop. The land was not given free to the settlers, but sold at the low price of from \$1 to \$2 per acre, to be paid to the government in from 7 to 10 years. The object in settling the southern states was not only to increase the population in the most thinly settled parts of the country, but to create a European population capable of raising European agricultural products in the region best adapted for that purpose. That would create a cheap food supply for the more northern states, which could then be entirely devoted to the cultivation of the more valuable tropical crops of coffee, sugar, etc.

The plans succeeded so well that the government was soon afraid of the preponderating influence of the German population in the south and began to favor the immigration of Italians and Poles, of whom about 100,000 came in the years 1890 and 1891. The liberal provisions of the law were not, however, carried out long, and the government confined itself later on only to granting free passage to the country, employing the newly arrived immigrants in road-building on the land which they were to settle. This naturally led to a decline in immigration, since the newcomers found it difficult, if not impossible, to save enough from their small earnings as laborers to buy land and cultivate it. In 1891 a new colonization law was enacted which favored colonization by strong financial companies willing to invest large sums of capital for the purpose. Any company could purchase from the government great tracts of land at 20 cents per acre, which were to be resold to colonists whom the companies were to bring into the country at their own expense. The government was to pay the companies a subsidy of \$230 for each family brought in, and \$700 additional for each mile of road laid out. The terms of the new law were so favorable that companies immediately formed and secured concessions for more than 150,000 square miles of land. But the political troubles which set in in 1893 put an end to financial aid by the government, which amounted to about \$25,000,000 until 1890. The total immigration during

1854-1904 was 2,096,576, of whom 1,030,000 were Italians, 465,000 Portuguese, 216,000 Spaniards, and 70,000 Germans. The highest number of immigrants was in 1891 (216,659), and the lowest in 1904 (12,447). In 1911 136,000 immigrants entered the country, of whom 48,000 were Portuguese, 27,000 Spaniards, 23,000 Italians, 14,000 Russians, and 4250 Germans.

Education is in an extremely backward state, especially in the interior of the country. Primary instruction is free, and every parish is supposed to possess one teacher for boys and one for girls, but education is not compulsory, and the pupils attending the schools constitute but a very small fraction of the population of school age. The percentage of illiteracy for the entire nation is over 80. In the cities the level of general culture is much higher, for they contain all the institutions of secondary and higher learning controlled by the federal government. At Rio de Janeiro are the two high schools, known jointly as the *Gymnasio Nacional*. Several cities have schools of medicine and schools of law and political science, and there are various military, engineering, industrial, agricultural, and technical schools. In 1910 there were 12,221 primary schools, with 634,539 pupils (352,418 boys, 282,121 girls). Of the schools 2695 were private, 2608 municipal, and 6918 government. In 1909 secondary schools numbered 327, with 30,258 students. The larger cities have museums and libraries, and the National Library at Rio de Janeiro has a magnificent collection of printed volumes, manuscripts, and iconographical exhibits, numbering, in all, over 525,000 pieces.

Religion. Church and state are entirely separated, but the government provides for the maintenance of the Roman Catholic religion, which is the faith of 99 per cent of the people. The country is divided into 11 episcopal sees, in each of which a theological seminary is located. The Archbishop of Bahia is metropolitan of the province, and under him are 11 bishops, 12 vicars-general, and about 2000 curates.

History. By the provisions of the Treaty of Tordesillas, signed by Portugal and Spain in 1494, most of the territory within the present limits of Brazil fell to the share of the former. Early in 1500 Vicente Yáñez Pinzón landed on the coast of Brazil, probably near Cape St. Augustine, and coasted as far as the Orinoco River, discovering the mouth of the Amazon. In the same year Pedro Álvarez Cabral landed at Porto Seguro and, taking possession of the country in the name of his monarch, gave it the name of Vera Cruz, later changed to Santa Cruz. In 1501 and 1503 the country was visited by expeditions under Amerigo Vespucci, who in the latter year left a garrison of 24 men behind him and returned with a cargo of brazilwood, which gave the vast region its name. The first permanent settlement was made by the Portuguese on the island of São Vicente in 1501, other colonies founded subsequently being abandoned on account of the hostilities of the Indians. Bahia was founded in 1549 and till 1763 was the capital of Brazil. The Huguenot settlement established in the Bay of Rio de Janeiro in 1558 was broken up in 1567 by the Portuguese, who founded the town of Rio de Janeiro. From 1580 to 1640 Brazil as a dependency of Portugal was in the possession of Spain, and in the latter part of this period the Dutch, who were at war with Spain, seized upon a considerable portion

of the country, which they held for some time. The fall of Bahia in 1624, under the attack of the fleet sent out by the Dutch West India Company, brought Spaniards and Portuguese together in an effort to regain the city. In this they were successful in 1625, with the aid of the natives. This incident had important sociological results, for the honors conferred upon the chiefs for their help broke down to a large extent the barrier between the two races, and to this day among the better classes of Bahia there is a greater admixture of native blood than is to be found elsewhere in Brazil. In 1630 the Dutch captured Pernambuco and retained the stronghold of Olinda till 1654. But even with this last stronghold gone, it was not until 1662 that Holland admitted its defeat and renounced by treaty with Portugal all territorial claims in Brazil, in exchange for a cash indemnity and a few trading privileges. In 1710-11 France made an invasion of Brazil that was only partially successful. Between Portugal and Spain there was a long-standing dispute concerning the possession of the eastern shore of the La Plata, which was not settled until 1828, when Brazil recognized the independence of the Banda Oriental. (See URUGUAY.) The discovery of gold in 1691 and of diamonds in 1710 resulted in the rise of a number of mining towns. The arbitrary colonial order under which Brazil had been settled was the so-called hereditary captaincy system (similar to the patron system in New York). Although it had been successful in Madeira and the Azores and was beneficial in the opening stages of Brazilian history, it did not work out well in the long run and is considered by some to have greatly retarded the progress of the country. In 1807, under the pressure of French invasion, the royal family of Portugal fled to Brazil, which remained virtually the seat of government until 1821, when King John VI returned, leaving his eldest son, Dom Pedro, as Prince Regent, but in the following year (Sept. 7, 1822) the independence of Brazil was proclaimed, and on October 12, the Prince Regent was crowned Emperor. Early in 1824 he took his oath to the constitution, and in 1825 the independence of Brazil was formally recognized by the Portuguese King. Dom Pedro soon became unpopular, and his unpopularity was only slightly diminished when, upon his father's death, he was unanimously recognized as King of Portugal. Nor did his prompt abdication of that crown in favor of his daughter Maria stem the rising tide of his unpopularity. Consequently, in 1831, he felt constrained to abdicate even the Brazilian Imperial crown in favor of his five-year-old son.

Under the regencies which followed, Brazil was plunged into disorder and political intrigue, and the result was that, as a reaction against republicanism, the young prince was declared of age in 1840, and in 1841, at the age of 15, was crowned Emperor, as Dom Pedro II. The only wars during his reign, aside from a few revolutionary outbreaks, were those waged against Rosas, the Dictator of Buenos Aires, in 1852 and against Paraguay in 1865-70. Pedro II was a patriotic and enlightened monarch. Among the events of his administration was the passage of an act in 1871 providing for the gradual abolition of slavery. The centralized system of government, however, and the general prevalence of corruption in the provincial

administration, excited a widespread feeling of discontent, especially in the army, and an attempt in 1889 to form a national guard under Imperial control hastened the crisis. On November 15 intelligence that Rio de Janeiro was in the hands of the insurgents reached the Emperor at his countryseat, and on hastening to the capital he found that the ministry had been deposed. Later in the day a provisional government, headed by Marshal Deodoro da Fonseca (qv), was organized, which issued a manifesto proclaiming a republic. All these changes met with little opposition, indeed, it had been long and widely believed that the Empire would not outlive the Emperor. Dom Pedro attempted to form a new ministry, but failed, and a new decree ordered him to leave the country with his family within 24 hours. The same decree continued the Imperial dowry and granted the Emperor a subsidy of \$2,500,000, both of which he refused. All his private possessions were respected, and his daughter continued to possess them. On the following day, November 16, the Emperor and his family embarked for Portugal, and the concession (November 21) of universal suffrage to all Brazilians that could read and write was followed by the appointment of a commission to draft a federal constitution. On Jan. 10, 1890, the separation of church and state was decreed by the provisional government. The new constitution (subject to further revision) was promulgated on June 23. In February, 1891, Marshal Fonseca was elected the first President of the republic, but before the close of the year his arbitrary proceedings provoked a revolutionary movement in Rio de Janeiro, which forced him to resign. He was succeeded by the Vice President, Gen. Floriano Peixoto. In 1893 a revolt, probably aiming at the restoration of the Empire, was headed by Admirals Da Gama and Mello and supported by the navy. Rio de Janeiro was blockaded and shelled by the rebels, but, owing largely to the unfavorable attitude of the United States, whose war vessels broke the blockade, the revolt (which was accompanied by insurrections in some of the states) collapsed early in 1894, and the insurgents fled or surrendered.

Peixoto was succeeded later in the same year by Dr. Prudente de Moraes. Another rising, headed by a religious fanatic, Antonio Conselheiro, broke out in 1897 in the state of Bahia. It was probably assisted financially to some extent by the partisans of the old Empire, and threatened for a few months to cause the government much trouble, but it was eventually crushed. An attempt to assassinate President Moraes on November 5 of the same year resulted in the discovery of an important plot against the existing government, which immediately collapsed. In November, 1898, Dr. Campos Salles succeeded Moraes as President. He was succeeded in 1902 by Dr. Rodrigues Alves. The frontier toward French Guiana was determined by a decision of the Swiss Federal Council in December, 1900. The dispute with Great Britain over the Guiana frontier was referred for arbitration to the King of Italy, whose award, rendered in June, 1904, gave about 19,000 square miles to Guiana and 14,000 square miles to Brazil. More important was the settlement in November, 1903, of the dispute with Bolivia over the Acre territory. Bolivia gave up all claims to Acre (73,750 square miles) in return for a cession of 886 square miles on the affluents of

the Abuna and Madeira, of 335 square miles on the left bank of the Paraguay, and a payment of \$10,000,000 to be expended by Bolivia on railroad construction in the border territory. Brazil also undertook to construct a railway along the rapids of the Madeira, connecting the upper and lower navigable portions of the river and thus aiding the foreign commerce of Bolivia. Complications now resulted between Brazil and Peru which advanced claims to the Acaré region, it was agreed to arbitrate the question. Dr. Afonso Penna was elected President in 1906. Marshal Hermes da Fonseca was elected President for the term 1910-14.

BRAZIL. A city and railroad centre, the county seat of Clay Co., Ind., 57 miles west-southwest of Indianapolis, on the Central Indiana, the Chicago and Eastern Illinois, and the Vandalia railroads (Map: Indiana, B 3). Block-coal mines in the vicinity are the field of the chief industry. The city has manufactures of mining engines and machinery, tile, pianos, tin products, wire fence and wire-fence machines, lathes, sewer pipe, pumps, and brick. An almost inexhaustible supply of clay and shale of superior quality opens up possibilities for an immense trade in clay products, the manufacture of which is already considerable. Brazil owns and operates its water works and has a Carnegie library. Settled in 1856, it was first incorporated in 1873. Under the present charter, Brazil is governed by a mayor, elected every four years, and a city council. Pop., 1890, 5905; 1900, 7786; 1910, 9340.

BRAZIL, ISLAND OF. See MYTHICAL ISLANDS.

BRAZIL CABBAGE (so called on account of its southern origin), or CHOU CARABE (*Caladium sagittifolium*, or *Xanthosoma sagittifolium*). A plant of the family Araceæ and native of the West Indies. It is extensively grown in Porto Rico under the name Yautia. The rhizomes are rich in starch and form an important source of food in the regions where it is cultivated; the leaves are also boiled and used as "greens." Both root and leaves are almost entirely destitute of the acidity so generally characteristic of the order.

BRAZILETTO WOOD. See BRAZIL WOOD.

BRAZILIAN COCOA. See GUARANA.

BRAZILIAN GRASS. An incorrect name applied to a substance used in the manufacture of a cheap kind of hats, known as Brazilian grass hats and also as chip hats. It consists of strips of leaves of a palm (*Chamarops argentea*), which are imported to Great Britain and elsewhere for this manufacture, chiefly from Cuba. See CHALMEROPS.

BRAZILIAN PLUM. See HOG PLUM.

BRAZIL NUTS, CREAM NUTS, or NIGGETTES. Seeds of *Bertholletia excelsa*, a majestic and beautiful tree of the family Myrtaceæ. It grows to the height of 100 or 120 feet and abounds on the banks of the Orinoco and in the northern parts of Brazil. It produces a round, woody pericarp, or seed vessel, almost as large as a man's head, within which are many of the seeds, or nuts. The pericarp is very heavy and solid, requiring the blow of a hammer to break it; when ready to fall, it is dangerous, on account of its weight, to walk under the tree. The seeds, which are popularly called nuts, vary from 18 to 24 and are wrinkled and triangular, having a hard shell and a pure-white kernel, which when fresh is very agreeable. They are chiefly exported from Pará and French Guiana and are well known in stores. They yield a large quantity of oil, which is good for burning. The nuts of the monkey-pot tree, *Leocythæ Ollaria* and *L. Zabucajo*, are produced in a pericarp which resembles a rusty iron pot with a lid, the lid dropping off and letting out the seeds, which are oblong, grooved, and esteemed superior to the common Brazil nut. They are sometimes known as Sapucaia nuts or Paradise nuts, but they have not yet become a common article of commerce, as the trees grow chiefly in the interior parts of the country. See accompanying Plate, and also Plate of BREADFRUIT, etc.

BRAZILWOOD. A dark-red or yellowish brown dyewood, which forms a considerable article of export from Brazil, where some of the trees which yield it are very abundant. It is the product of a different species of *Cesalpinia*. The best kinds are those called Pernambuco wood, All Saints' wood, and St. Martha wood. Some confusion exists as to the exact botanical identity of the different varieties of brazilwood. Much of the brazilwood of commerce is obtained from *Cesalpinia brasiliensis*, a tree which is a native of the West Indies, commonly growing in dry places and among rocks, and seldom exceeding 30 feet in height. It has bipinnate leaves, with many smooth, obtuse, oblong leaflets and no terminal leaflets, the flowers in panicles, with downy stalks. The heartwood alone is of any value. Pernambuco wood is the product of *Cesalpinia echinata*. The sapwood is extremely thick, and the valuable heartwood bears a small proportion to the whole diameter of the

BRAZIL NUT, ETC.

1. BUTTERNUT (*Juglans cinerea*).
2. BROOM CORN (*Sorghum vulgare*).
3. BUCKBEAN (*Menyanthes trifoliata*).

5. BUCKWHEAT (*Fagopyrum esculentum*).
5a. BUCKWHEAT, enlarged grain.
6. BRAZIL NUT, LEAF AND POD (*Bertholletia excelsa*).

stem. The sapan wood (qv) of the East Indies nearly approaches brazilwood in quality. It is the product of *Casalpinia sappan*, a small, thorny tree. The brazilletto wood, sometimes also called brazilwood, which is brought from the Antilles, is much inferior. *Casalpinia crista* probably yields some of the inferior West Indian brazilwood. Brazilwood is said not to take its name from Brazil, but to be mentioned under the name Braxilis in documents much older than the discovery of America, the sapan wood of the East Indies being probably intended.

When freshly cut, the color of brazilwood is yellow, but when exposed to air, moisture, and light, it becomes red, and is generally sent into market ground down to the size of ordinary sawdust. When treated with water, alcohol, or ether, the weathered brazilwood readily yields up its red coloring matter, called "brazin." Strong decoctions of brazilwood are used by the dyer and calico printer in the fabrication of reds, browns, etc. It is also used in the manufacture of red ink and as an indicator in analysis, alkalies changing the solution to bluish violet and acids to yellow. Brazilwood as a dyestuff has been largely superseded by synthetic dyestuffs. See INK.

BRAZING, braz'ing, or BRASS SOLDERING

The process of uniting two pieces of brass, copper, cast iron, malleable iron, steel or common iron, or one of each, by means of a hard solder, partaking more or less of the composition and properties of ordinary brass. (See ALLOY.) The edges or parts of metal to be joined are first filed bright, so as to be thoroughly clean, then there is strewn over the gap or crevice a mixture of the solder and borax, or some composition including boracic acid, and then heat is applied. In some cases the parts to be united should be heated before the flux (which should be appropriate to the particular joint in hand) and brass are applied. In brazing a form of solder appropriate to the kind of work is employed, those used for the purpose varying considerably in composition. (See SOLDER.) Most of these solders consist of alloys of copper and zinc, though sometimes tin and other metals are added. The various metals are fused together, allowed to cool, and then filed down to a coarse powder, in which form the solder is used. The borax or other flux is employed to form a glaze over the brightened surfaces and thus prevent the oxidation of the metal, which would seriously interfere with and even stop the operation. An outward coating or layer of charcoal is likewise serviceable in the exclusion of the air during the brazing of large pieces of metal. Where a very high heat is required in the process, a little powdered glass is mixed with the borax. The mixture of solder and borax may be applied dry, but it is better to moisten it with water and to lay it on the filed surfaces with a spoon. The whole is then gently heated, when the water evaporates, and a crust of borax and solder is left. The work may now be strongly heated before the blowpipe or over a clear fire, and at a bright-red heat the solder fuses and the zinc begins to burn with a pale-blue flame. At this stage the solder flushes or becomes liquid enough to permeate the joint or crevice, but should it be tardy in acting thus, several slight taps will insure the proper result. The whole is now cooled, and toward the close of this process the articles may be introduced into cold water for more rapid reduc-

tion in temperature. Pieces of metal which have undergone the process of brazing are so firmly united that they may be rolled and re-rolled without the parts yielding.

BRAZOS, bra'zós (Sp. pl. of *brazo*, arm, so called on account of its being formed by the two confluents.) One of the largest rivers of Texas, formed by the junction of Clear and Salt forks, in Young County (Map Texas, D 4). It flows southeast in a tortuous course and empties into the Gulf of Mexico about 40 miles to the southwest of Galveston. It is about 900 miles long and drains a very extensive area. It is navigable during high water for a distance of 300 miles from its mouth and at all times to Columbia, 40 miles from the Gulf. It flows through a generally fertile country, the lower part of its course being through alluvial deposits.

BRAZOS DE SANTIAGO, dà san'te-á'gò. A port of entry in Cameron Co., Tex., on Brazos Island, Gulf of Mexico about 35 miles northeast of Brownsville (Map Texas, D 4). It has considerable coasting and foreign trade, the latter being valued at about \$1,260,701 in 1912, of which over 80 per cent were exports. A shifting sand bar, which rarely admits vessels of over 10 feet draught, is a hindrance to the commerce of the port.

BRAZZA, brat'sa (Slav *Brac*, from Lat. *Brattia*, *Brattia*, *Brachia*). The largest island of the archipelago forming a part of Dalmatia, Austria-Hungary, in the eastern part of the Adriatic Sea, about 8 miles south of Spalato (Map Austria, E 5). Area about 150 square miles. The surface is somewhat mountainous, but the soil is fertile, and olives, figs, grapes, almonds, saffron, and silkworms are cultivated. It has celebrated marble quarries. Pop., 1900, 24,465, 1910, 22,967. The chief towns are San Pietro, Milna, Bol, and Neum. The island forms a separate administrative division of Dalmatia.

BRAZZA [PIERRE PAUL FRANÇOIS CAMILLE], SAVOIGNAN, COMTE DE (1852-1905). A French explorer born on board a vessel in the harbor of Rio de Janeiro. He was educated at the French Naval Academy, became a naturalized French citizen, and entered the navy in 1870. After several years of service in West Africa he attracted attention by exploring the Ogowe River (1876-78). He found that the Ogowe and Alima rivers, with a land portage between them of 25 miles, offered a route between the upper Congo and the sea. In 1879 he founded two stations as bases of supplies for his new route—one (Francenville) on the upper Ogowe, the other (Brazzaville) on the Congo itself. In 1880 he made a treaty with King Makoko, who put his possessions under French protection and ceded to Brazza the site for his station, Brazzaville. Later he discovered a route by way of the Niari River which supplied a shorter water route between Brazzaville and the coast. He established stations and won over the natives to French allegiance. In 1886 he was made Commissioner General of the government in French West Africa. Reappointed in 1897, he introduced various reforms and put steam launches on the Congo and the Ogowe. He was very tactful and had great influence with the natives. Illness compelled him to return to France, but in 1890 he accepted the appointment of Commissioner General of the entire French Congo, with Gabon under his direct authority. In 1897 he went back to live in France. It

was due chiefly to his gifts as explorer, organizer, and administrator that the French Congo was added to France's domain. In February, 1905, he was sent by the French government to the Congo region to investigate charges of brutality on the part of French officers toward the natives and seemed to have established the truth of some of these accusations. He was returning from this mission when he was taken ill at Dakar, where he died (Sept. 15, 1905).

BREACH (ME. *breache*, fracture, from *break*; AS. *brecan*, just as *speech* is from *speak*). In military siege operations, a gap made in any of the defensive works of a fortified position or intrenchments, or in the walls or gates of a city. Before the introduction of modern high-power guns the most elaborate tactics were employed to obtain this result. Breaching batteries were used to destroy walls by directing and lodging the shot or cannon balls in two vertical lines, from the parapet of the wall downward, and in a horizontal line, connecting the lower ends of those vertical lines, thus overturning the weakened part and enabling the besiegers to attempt an entrance by the breach so made. Notable and historic examples are to be found in the Peninsular War (1808-14), when at Badajoz 14,000 shot, fired from a distance of 450 yards, brought down 180 feet of wall in 104 hours. At Ciudad Rodrigo 6700 balls, from a distance of 560 yards, reduced 105 feet of wall in 32 hours. At San Sebastian 13,000 shot brought down 100 feet of wall in 62 days from a distance of 620 yards. At Fort Pulaski (1862), in the American Civil War, it is estimated that in breaching the brick wall of the fort, 110,000 pounds of metal from 38 guns struck it in the course of a two days' bombardment from an average distance of 1687 yards, making an average of 2500 pounds to the square foot. The term "breach" is also applied to an opening made by attack in a line of defense, even when it is unfortified. See SIEGE and SIEGEWORK; FORTIFICATION.

BREACH. In law, the violation of a legal obligation, whether voluntarily assumed or imposed by law. The obligation may be personal, i.e., imposed upon or assumed by a certain individual, as the duty of support of wife and children resting upon a husband or father, or the obligation of a person under a contract by which he has bound himself, or it may be general, i.e., imposed by law on the entire community or upon a class of persons, as the duty of each and everybody to refrain from trespassing upon private land or from violating the peace and security of the state. In the former class of cases, known as obligations in personam, the breach can be committed only by the specific individual upon whom the obligation rests; in the latter class of cases known as obligations in rem, i.e., with respect to a certain thing or a certain right of an individual or the state, the liability for the breach falls upon any one who may happen to violate the obligation.

A breach may consist either in an act violating a public or a private duty or, negatively, in the neglect or refusal to perform an act which one is under a duty to perform. The consequences of a breach are various, depending on the nature of the obligation violated. In the case of an absolute right, as the right of a possessor of land to be protected against an invasion of his possession, any entry on his land,

however innocent and unintentional and whether resulting in damage or not, constitutes a breach of his possession, whereas other rights, which may be called relative, as the right of a property owner to be free from nuisance, are infringed only by acts which inflict a material injury.

A breach of whatever sort and by whomsoever committed gives rise ipso facto to what is known as a remedial right in the party, whether the state or an individual, whose right has been infringed, i.e., to the appropriate legal proceedings for the protection or vindication of the right. Breaches of a public duty are usually, though not always, punishable as crimes. Sometimes they involve only forfeiture of goods or a penalty to be recovered by a civil action, or the summary action of a court of equity as for a contempt. Breaches of private obligations—classified as breaches of contract, quasi contractual obligations, torts, quasi delicts and breaches of trust—are usually punishable by an action for damages and sometimes also by a decree in equity, restraining or directing the performance of an act. Certain acts, classified as torts or private wrongs, may at the same time be public offenses and, as such, punishable by the criminal law, as libel, assault and battery, and breach of trust.

It is a characteristic of our system of remedial justice that its remedies are not generally available until after a breach of legal obligation has been committed and the injury involved therein sustained at least in part. In other words, the courts exercise a remedial, not a preventive justice. This is true even of the equitable remedies of specific performance of contracts and specific reparation for torts, the breach of contract or the infliction of the wrong known as a tort being a condition precedent to the right to invoke the remedy. However, as is obvious from the nature of these remedies, the breach need not be complete, nor, in the case where the remedy in equity is sought against a tort, can it have been complete, for the object of the proceeding is to restrain future breaches like those already committed, as in the case of continuous nuisances or repeated acts of trespass.

Not every act which results in harm to another is punishable as a breach. Thus there are many such acts, which may or may not be morally reprehensible, for which the law affords no remedy, as the withdrawal of subterranean waters from a neighbor's land or the sacrifice of another's life to save one's own. To the consequences of such acts as these the phrase *damnum absque injuria* (damage without legal injury) is applied.

For specific illustrations of the principles above laid down, see: BREACH OF CLOSE; BREACH OF CONTRACT; BREACH OF PROMISE; BREACH OF TRUST; BREACH OF PEACE; BREACH OF WARRANTY; CRIME; QUASI CONTRACT; TORT; SPECIFIC PERFORMANCE; DAMAGES.

BREACH OF CLOSE (OF, and Fr. *clos*, an inclosure, from Lat. *clausus*, p.p. of *claudere*, to shut, close). The technical legal phrase to describe the wrongful act of entering without authority on land in the possession of another. It is the *gravamen*, i.e., the substantial ground, of the action of trespass. The possession of land is so jealously guarded at the common law that the possessor's premises are regarded as a close (*clausum*, an inclosed place) and any invasion of the possession as a "breaking and en-

teing." Accordingly the writ of trespass, whereby the action was formerly instituted, commanded the defendant to show cause why he had broken the plaintiff's close (*quare clausum quarentis fregit*) and concluded, as in criminal informations, that the act complained of was contrary to the peace of the king (*contra pacem regis*). As a matter of fact no actual breaking of an inclosure was ever requisite to constitute the offense, the breach consisting, as it still does, in the mere act of being unlawfully, i. e., without authority, on the land of another, however the entry may have occurred, unless it was due to inevitable accident. Nor need the wrongdoer, in fact, enter upon the premises in person. It is enough to discharge water, or throw a stone upon another's land, or send one's dog upon it, or negligently permit one's cattle to invade it, to constitute a breach of close. See **TRESPASS** and the authorities there cited.

BREACH OF CONTRACT The failure, deliberate or unintentional, to do any lawful thing which one has bound himself by contract to do. It is not every non-performance, however, which results in a breach of contract. In certain cases, if the contractor has acted in good faith and has substantially performed, it has been held that a slight deviation from the contract will not constitute a breach thereof. This principle is of frequent application in the adjustment of rights under building contracts. The consequences of a breach depend on the nature of the contract and upon the character of the breach. In a unilateral or one-sided contract, i. e., where only one of the parties is under an obligation to do or not to do a specified thing, a breach entitles the other party, at his election, either to disaffirm the contract and recover the consideration given by him therefor, or to an action for the damages resulting to him from the breach. In bilateral contracts, on the other hand, where both parties are bound to performance, the default of one entitles the other to an action for damages and, in some cases, also to disaffirm the contract and refuse to perform or to complete performance on his part. The latter remedy is available only in case performance by the party not in default is dependent on due performance by the party in default. Thus happens where performance by one party is made a condition of performance by the other, or, as it is commonly expressed, where a term or stipulation is expressly declared or is construed by the court to be "of the essence" of the contract. Thus the time of payment of a sum to be advanced by a party is not generally of the essence of a contract, but it may be expressly declared so to be, or it may from the nature of the contract appear to have been so intended. In certain cases, as in an agreement for the conveyance of land, the party not in default may have a decree of specific performance, directing the defaulting party to perform.

To constitute a breach of contract it is not necessary that a demand of performance be made, either before or after default, and that such performance be formally refused. Indeed, it is now settled in England, in the United States Supreme Court, and the courts of many of the States, though the doctrine is repudiated in Massachusetts and a few other States, that one may be guilty of a breach of contract before the time for its performance has arrived.

For example, a person contracts to sell and convey certain property at a future time. Before that date he notifies the other party that he will not carry out the contract, or he sells and conveys the property to a third person. He is liable for an "anticipatory breach," as it is called. This doctrine proceeds upon the theory that the parties of a contract have the right to the maintenance of it up to the time of performance, as well as to its performance when due. See **BREACH, CONTRACT, SPECIFIC PERFORMANCE**, and the authorities there referred to.

BREACH OF PROMISE The popular expression for the violation of an agreement of marriage. The rights and obligations of the parties to a marriage are not contracted in character, but are imposed by law as an incident of the marriage relation. But the agreement of a man and woman to enter into that relation is a simple contract, the promise of the one party being the consideration for that of the other. There may be other considerations, as a conveyance of property or a promise to make such a conveyance, but the contract of marriage, as it involves the union of two parties in a new relation, is unique in this respect, that it necessarily involves the exchange of mutual promises of marriage. It falls, therefore, into the class of *bilateral* contracts. As the contract may now generally be entered into informally, i. e., without a writing or a ceremony of betrothal, so it may be varied from time to time, as by a change in the date of performance or may even be abrogated in the same way, without writing or other formality.

The contract of marriage is subject to the ordinary rules governing the validity of contracts in general. Both parties must be of sufficient mental capacity to contract, and both must have reached the age fixed by statute as the "age of consent." A contract made by a minor who has reached the age of consent is not void but is voidable by him at his election, but cannot be avoided by an adult who has entered into such an engagement with him. Impossibility of performance, whether existing at the time the contract was made or subsequently occurring, excuses both parties. It appears to be settled in England that bodily infirmity or unfitness of the defendant will not excuse his or her breach of this contract, although it will warrant the other party in refusing to perform the contract. In the United States it has been held that incurable physical unfitness for the marital relation, arising subsequent to the betrothal, is a legal excuse for refusing to marry. Chastity and modest conduct is a condition subsequent, by the breach of which the defendant is released from his obligation. If one party induces the other to enter into a contract to marry by fraudulent representations, the party defrauded may maintain an action in tort for the damages sustained. But ordinarily an action for breach of promise is a contract action, although it has many of the characteristics of a tort action. For example, at common law, the right of action does not survive the death of either party to the contract, in the absence of special damage to the personal estate of the deceased, such as expenditures made in contemplation of marriage and lost by reason of the breach, the plaintiff may recover punitive damages, under many statutes the defendant is liable to arrest as though he were charged with fraud, and if a judgment is recovered against

him, execution may issue against his body. Ordinarily, however, the only remedy for breach of promise is an action for damages. The equitable remedy of specific performance is never granted. Repeated attempts have been made in England to abolish actions for breach of promise to marry by act of Parliament. Although these attempts have been unsuccessful, it is declared by English writers that breach-of-promise suits have not borne as abundant harvests in England as in the United States. The action may be brought by either party, but suits by men for breach of promise are rare. For further particulars see MARRIAGE, BETROTHAL; CONTRACT; TORT, and the authorities there referred to.

BREACH OF THE PEACE. In the most general sense, any violation of the peace and order of the state, i.e., any criminal offense. The "king's peace" denoted the state of order maintained by the royal authority—originally, perhaps, only in the palace and its immediate vicinity, then throughout the territory in which the king's writs ran and his itinerant justices exercised the royal jurisdiction. So every territorial lord had his "peace," which was coextensive with his manor or lordship, every sheriff had his, which extended over the county in which he exercised jurisdiction. Any act which violated the peace of the king, the lord, or the sheriff was punishable in the court and by the law of the king, of the manor, or of the county, as the case might be.

As the local law often differed in important respects from the general law of the land, for example, the law of the manor in which the offense was committed from the common law of the realm, an act might be a breach of the lord's or the sheriff's peace and yet not a violation of the king's peace. Where, as was usually the case, the act complained of was at one and the same time a breach of the local and of the general peace, it was *prima facie* punishable in the local court, unless the accusation asserted that the act was a violation of the peace of the king (*contra pacem regis*), when the king's court would *ipso facto* acquire jurisdiction to the exclusion of that of the local tribunal, and the offense become punishable by the common or statute law of the realm instead of by the local law.

In modern usage, breach of the peace is employed to describe certain specific offenses in which the public order is disturbed, such as rioting, disturbing a lawful meeting, taking part in an unlawful assembly, engaging in a prize-fight, unlawfully discharging firearms in a public place, and the like. Formerly in England participation in an unlawful assembly of 12 persons or more constituted a breach of the peace, only, however, if the participants refused to disperse after being ordered by proclamation so to do. As the proclamation included the reading of the Statute of 1 Eliz., c. 16, relating to rioting, the practice came to be known as "reading the Riot Act." Under modern statutes, in this country as well as in England, no proclamation is necessary to fix the liability for a breach of the peace by rioting or unlawful assembly.

A person shown to be likely to assault or persistently annoy another may be required to give security for his good behavior. Though the act threatened may not be a breach of the peace in the modern sense of the term, the process is

commonly described as putting the wrongdoer under bonds to keep the peace.

See ASSEMBLY, UNLAWFUL; RIOT, and the authorities there referred to.

BREACH OF TRUST. The violation by any one in a fiduciary relation to another of the legal or equitable duties imposed by virtue of that relation, specifically the violation by a trustee of any of his obligations of his trust. Such breach may take on a variety of forms, but is usually committed by the neglect or refusal of a trustee to pay to the beneficiary a sum of money payable by the terms of the trust, or to convey to the beneficiary (technically called the *cestus que trust*) or to a person designated by him, property to which he is entitled, or by the alienation to a stranger of property which it is the duty of the trustee to hold for the beneficiary, and generally by any mismanagement of the property held in trust. A breach of trust may render the trustee liable to respond in damages, or to removal from his trusteeship, or to criminal prosecution, according to the nature of his misconduct. Some modern statutes have so extended the crime of larceny (*qv*) as to include a breach of trust, if the latter consists in secreting, withholding, or otherwise converting to the trustee's own use, property which has come into his possession by virtue of his trusteeship. See TRUST; TRUSTEE.

BREACH OF WARRANTY. A violation of a contract guaranteeing the validity and soundness of the title to real property and agreeing to protect the same against any lawful claim to the property that may be set up by the warrantor or any other person. Such contracts are an ordinary incident of conveyances of land and may be made by the grantor or by another. They belong in the class of contracts known as "covenants running with the land" and may accordingly be enforced not only by the covenantee or immediate grantee, but by any subsequent holder of the land who derives his title from such grantee. Although the title to land conveyed may at the time of the warranty be defective, there is no breach until the person claiming under such title is evicted, either by the grantor or those claiming under him or by a third person under a lawful claim of title. The covenant does not protect the covenantee or grantee or his successors against unfounded claims unless asserted by the covenantor or grantor. The remedy for the breach is an action for the damages sustained in consequence of the eviction of the person protected by the covenant and usually consists of the price paid for the property with interest. See DEED; TITLE; WARRANTY.

BREAD (AS. *brōad*, Icel. *braup*, Ger. *Brot*, akin to AS. *brocnean*, Eng. *brew*, *broth*). Cereals of some kind or other have always made an important item of human food, and of all the forms in which they have been used bread has proved the most satisfactory. Wheat, rye, corn (maize), and oats are commonly used for bread making; less commonly, barley, buckwheat, rice, etc. To prepare the grain for bread making it is usually cleaned, crushed, and bolted to obtain a fine, soft powder called flour or meal. The flour is made into a dough with water and baked. Sometimes the dough is made with milk, or milk and water. Salt is usually added and often a little sugar and lard or butter. If the dough is fermented or leavened in any way be-

fore baking, the resulting product is called leavened bread. If no leavening agent is used, unleavened bread results. The common leavening agents are yeasts, both wild and cultivated, leaven, i. e., dough saved from a previous baking, and chemical mixtures or baking powders. The bread most commonly eaten in the United States, and often called white bread, is made, whether at home or at a bakery, from some one of the high grades of wheat flour or from a mixture of two or more grades. It is usually leavened with yeast.

The primitive way of making bread was to soak the grain in water, subject it to pressure, and then dry it by natural or artificial heat. An improvement was to pound or bray the grain in a mortar, or between two flat stones, before moistening and heating. A rather more elaborate bruising or grinding leads to such simple forms of bread as the *oat cakes* of Scotland, which are prepared by moistening oatmeal with water containing common salt, kneading with the hands upon a baking board, rolling the mass into a thin sheet, and then heating before a good fire or on an iron plate called a girdle, which is suspended above the fire. In a similar manner the barley-meal and pease-meal *bannocks* of Scotland are prepared. In Eastern countries, as well as in Scotland, wheat flour is kneaded with water and rolled into thin sheets called *scones*. The most interesting of the unleavened breads is, perhaps, the Passover bread, which has been used during Passover week by orthodox Jews from the time of Moses until now. It is simply a mixture of flour and water baked in small round cakes until it is dry and hard, and is not unlike plain water crackers. Pilot bread, or ship's biscuit, is another simple preparation of flour and water, so cooked that it can be kept for almost any length of time. Crackers, or biscuits, as they are often called, especially in England, are varieties of unleavened bread. Milk, butter, lard, spices, dried fruits—anything or everything desired to give them particular consistency, color or flavor—is mixed with the flour and water, and the dough is then passed through very ingenious cutting machines and quickly baked in a hot oven. Such crackers are a concentrated form of nourishment, as they contain little water in proportion to their bulk and are fairly solid in consistency.

Leavened or fermented bread is rendered light and porous by carbonic-acid gas, which distends it. This is provided (1) by the use of leaven or of yeast, which causes the carbonic acid to form by the action of fermentation, or (2) by the use of baking powders, which supply the necessary carbon dioxide to the dough by chemical reaction, or (3) by adding the gas to the dough directly, as in aerated bread. Leaven is simply dough, or a mixture of flour, which is in a state of fermentation. The knowledge of its action may have been accidentally discovered by attempting to combine with a fresh mixture dough which had been left over from a previous baking. It is probable that the use of leaven was first known to the Egyptians, that the Greeks and Jews learned it from them, and the Romans from the Greeks. Through the Romans this knowledge was spread far and wide through the subject nations which came under their influence. This method of bread making is still extensively employed in certain parts of Europe. Great care and skill are required in the making of leavened bread. There is always dan-

ger that during the process of fermentation lactic acid and other products which are disagreeable to the taste will form along with the carbonic-acid gas, then, if the leaven stands too long, it will reach the state of putrid fermentation.

With the knowledge of the yeast plant (see YEAST), first applied to beer making, the method of making fermented bread has been changed by substituting yeast for leaven. The action of the yeast plant—like that of leaven—when brought into contact with flour and water is to develop carbon dioxide and alcohol, the latter passes off in the oven in the form of vapor, the former is largely retained in the dough. The lightness of the bread depends upon the amount of this gas which remains imprisoned in the dough and distends it, hence it is due to the tenacity with which the grains of flour cling together, or, in other words, to the stickiness of the flour. It is in this respect that the superiority of wheat flour over that from all other grains lies. The sticky gluten of wheat does not allow the gas to escape. For this reason the quality of bread made from less tenacious flour is improved by mixing with it a portion of wheat flour.

The chemical reactions concerned in bread making and the conditions under which they are produced are easily understood. The process consists in adding to the flour and warm water the necessary amount of yeast. The yeast may be added directly or a preliminary ferment may be formed by mixing it with potatoes. If the latter method is employed, the yeast is put into a thin liquor, formed by mixing mashed potatoes with warm water, and the mixture is allowed to ferment for some time. The advantages claimed for the potato ferment are that "the yeast cells are strengthened by the soluble nitrogenous matter of the potato, which acts as a yeast stimulant and enables a smaller quantity of yeast to hydrolyze a larger amount of starch. The yeast cells then act very rapidly on the glucose thus produced from the starch and develop the alcoholic fermentation." The proportion of water required to mix with the dough and yeast to form the "sponge" depends upon the quality of the flour, as the gluten flours take much more water than the starchy flours, but enough should be added to make the sponge as moist as can be molded readily with the hands. The dough should be thoroughly kneaded, so that the yeast will penetrate to every part of the mass. It should then be allowed to stand in a warm place, for a proper temperature is an essential condition to the fermenting process. The most favorable temperature is from 70° to 75° F., if it is allowed to rise above 90° acetic, lactic, and possibly other organic acids are liable to form, in other words, the bread sours. If, on the other hand, the temperature is too low, the process of fermentation will not take place. The yeast begins to act upon some of the starch of the flour, changing it to sugar, and then decomposing the sugar into carbon dioxide and alcohol. It is not until the second stage is reached, and the gas begins to form, that the action is visible. After the process has gone on for a time, until the whole mass is honey-combed, the dough should be subjected to a second thorough kneading, to break up the large gas bubbles into many small ones and distribute them evenly through the mass of dough. The thoroughly kneaded mass is next molded

into loaves and allowed again to "rise." As bread loses a portion of its nutritive properties each time it is molded, the process should not be repeated too often. Bread which has been kneaded only once has a sweeter flavor than that molded twice, but its texture is coarser and its appearance less attractive. The loss of nutritive value is from that portion of the starch which is converted into alcohol and gas.

When the bread is thoroughly kneaded the second time, it is ready for the oven after rising. The best temperature for baking bread is from 450° to 550° F., so that the interior of the loaf will be at the boiling point, or 212° F.

moist crumb retains its heat much longer. As gradually, however, its temperature falls to that of the surrounding atmosphere, its moisture tends to pass outward, leaving a comparatively dry crumb and moist crust. Common experience shows that if stale bread is put into the oven for a few minutes it regains something of its fresh consistency—crisp crust and moist crumb. Such bread lacks the elasticity of the fresh loaf, and its interior crumbles as easily as before it was reheated. This is supposed to be because the starch has undergone a chemical change, the nature of which is not yet clearly understood. Indeed, the whole question of stale-

KIND OF BREAD	Water	Protein	Fat	CARBOHYDRATES			Ash
				Starch	Sugar	Dextrn, etc.	
Rye bread (German) {Crumb	46.4	8.9	.6	34.2	1.4	8.3	..
{Crust	12.5	12.3	.6	53.5	4.2	16.0	...
Wheat bread (German) ... {Crumb	40.6	6.5	1.0	40.3	2.5	8.9	...
{Crust	13.0	9.3	.6	59.2	3.6	14.0	...
Wheat bread (American) {Crumb	40.6	8.9	.5		49.7		.3
{Crust	22.3	11.4	.6		65.3		.4

During the process of baking the starch of the flour is rendered soluble by the heat, the fermenting growth is killed, and the alcohol formed by the fermenting action is driven off. The carbon dioxide is also expanded. By wetting the loaves before they are put into the oven, the crust is formed more rapidly, and the too rapid expansion of the dough is checked. Steam is sometimes injected into the oven while the bread is baking, thus glazing the crust and keeping the interior of the bread more moist. Baked bread consists of two portions, the crumb and the crust, which differ from each other both physically and chemically. These differences are due to the more sudden and intense heat to which the crust is subjected. The action of the heat and of the steam rapidly decomposes the starch into dextrin and maltose, which are caramelized by the heat, and so the surface takes on a brown color and a sweeter taste. The accompanying table shows the chemical difference between the crumb and crust of bread, according to the analyses of German and American investigators.

That fermented bread is more healthful than unfermented is the general opinion among physicians. Being porous, it is easily masticated and more thoroughly aerated during the process, so that the starch is more easily acted upon by the digestive fluids.

Good fresh bread has a crisp crust which breaks with a snap, and an elastic crumb which springs back into shape after being pressed with the finger. Before bread is a day old, however, its texture has changed; its crust has become softer and tougher, while the inside seems dry and crumbly; the bread is "growing stale," as we say. This was formerly supposed to be due simply to the drying of the bread; but as the loss of water is found by experiment to be comparatively slight, some other explanation is necessary, and various ones have been offered, of which the most interesting seems that given by Bouteux. He maintains that the apparent dryness is due to a shifting of the moisture from the crumb to the crust. When first taken from the oven the dry crust cools quickly, but the

ness is one about which little has been absolutely proved.

The average percentage composition of a number of common kinds of bread is shown in the following table:

AVERAGE COMPOSITION OF A NUMBER OF DIFFERENT KINDS OF BREAD

KIND OF BREAD	Water	Protein	Fat	Carbohy- drates	Ash
	%	%	%	%	%
Corn bread (johnnycake)	38.9	7.9	4.7	46.3	2.2
Rye bread	35.7	9.0	0.6	53.2	1.5
Rye-and-wheat bread	38.3	11.8	0.3	51.5	1.0
Wheat bread, "graham"	35.7	8.9	1.6	52.1	1.5
Wheat bread, "roll"	29.2	8.0	4.1	56.7	1.1
Wheat bread from high-grade patent flour	32.9	8.7	1.4	56.5	0.5
Wheat bread from regular pat- ent flour	34.1	9.0	1.3	54.9	0.7
Wheat bread from bakers' flour	39.1	10.6	1.2	48.3	0.9
Wheat bread from low-grade flour	40.7	12.6	1.1	44.3	1.3
Wheat bread, average of a large number of analyses	35.3	9.2	1.3	53.1	1.1
Whole-wheat bread	38.4	9.7	0.9	49.7	1.3
Crackers	6.8	10.7	8.8	71.9	1.8

It will be seen that wheat bread from low-grade flour, wheat bread from bakers' flour, and rye-and-wheat bread contain the largest amount of protein; corn bread and wheat rolls, the most fat; and wheat rolls, wheat bread from high-grade patent flour, and wheat bread from regular patent flour, the most carbohydrates. The amount of fat would, of course, vary greatly with the amount of shortening added in making the bread, and the examination of a large number of analyses of the same kind of bread has shown that the amount of each of the several nutrients varies in the same sort of bread within rather wide limits. Judged by their composition, all breads are nutritious foods, and too great stress should not be laid on the variations in composition between the different kinds.

The chemical composition of the finished loaf

differs somewhat from that of the original material, as is shown by the following table, which compares flour and the breads made from it

AVERAGE COMPOSITION OF WHITE BREAD AND OF THE FLOUR FROM WHICH IT WAS MADE

	Water	Protein	Fat	Carbohydrates	Ash
	%	%	%	%	%
Bread	35.3	9.2	1.3	53.1	1.1
Flour	12.0	11.4	1.0	75.1	0.5

The increase of water in the bread hardly needs explanation, since it is evidently due to the water added in making the dough. The use of butter or lard and salt probably accounts for the excess of fat and ash. The decrease in the proportion of protein and carbohydrates is due to the increase in the other ingredients, though a small quantity of each doubtless went to nourish the yeast. Most of the carbon dioxide into which they were converted passed out of the bread. According to Birnbaum the baked bread contains an average of 0.314 per cent of alcohol, by no means all of that generated by the yeast (about 1 per cent according to Snyder), part is evaporated and part is probably changed into acetic acid. The bacteria and other microscopic plants which accompanied the yeast doubtless took their share of the protein and carbohydrates, returning a part in the form of the characteristic acids and other bodies which they produce. Part of the starch in the crust has been changed into dextrin, and that in the crumb has become gelatinous or partly soluble. The gluten has taken definite shape, in other words, it has coagulated very much as the white of an egg does in boiling.

Effect of Baking Powders. Various mixtures of acid and soda called baking powders (qv) are prepared by which carbonic acid may be introduced directly into the dough, instead of awaiting the slower process of fermentation. By this means there is no loss of nutritive qualities in the bread by decomposition, while in fermented bread this amounts to 1 per cent. One of the disadvantages of this method is that in the case of most of the acids used to liberate carbonic acid from soda, the reaction is instantaneous, and much of the gas is dissipated before the bread reaches the oven. Cream of tartar is the only acid substance which does not liberate the gas by simple contact in the cold, it is therefore best adapted to cooking. Another objection to this method of raising bread is that a residue of harmful salts may be left in the bread. Hence it is that the various baking powders on the market should be used with caution. When cream of tartar and soda are put in separately by the cook instead of a baking powder, care should be taken not to use an excess of the former, as the flavor may be injured and the product be unwholesome.

Self-raising Flours are simple flours into which acid and soda preparations have been mixed in such proportions that the addition of water, by liberating the carbon dioxide, produces a spongy dough. Lightness is produced in bread or cake by the simple addition of well-beaten eggs, because the air is caught by the sticky albumen of the eggs and remains imprisoned in

the dough. Air at 70° F expands to three times its bulk when the temperature is raised to 500° F, and the whole mass of dough is expanded with it. If the heat of the oven is too intense when dough thus prepared is placed in it, the bubbles of air will swell so rapidly that they will burst, and the dough will fall.

Besides the ordinary white wheat bread, there are innumerable fancy white breads, breads made from flours other than wheat, and unleavened breads, on the market, which can hardly be more than referred to here. Most like the ordinary bread are the fancy white breads, such as Vienna and French rolls, the milk breads, etc. These usually differ chiefly in the use of milk, sugar, butter, lard, etc., in the dough. Entire wheat, graham, rye, barley, or oatmeal flours are made into bread in essentially the same way as ordinary wheat flour and vary in texture and nutritive value according to the composition of the materials from which they are made.

The original *graham bread*, made without yeast from graham flour according to the recipe of its inventor, and not to be confounded with raised graham bread, is made by kneading the flour and water thoroughly and allowing the dough to stand several hours before baking. It is heavier than ordinary yeast bread, but still is somewhat porous, owing probably to fermentation started by bacteria accidentally present in the flour and acquired from the air, it is sweet and by no means unpalatable, but probably the nutritive value of its protein is lower than Dr Graham supposed.

Gluten bread, if properly made, contains the gluten of the flour, from which more or less of the starch has been removed. To make it, strong flour and water are made into dough, which is pressed and stained under a stream of water until the starch has been worked out, it is then kneaded again and baked. It makes a light, elastic loaf, frequently prescribed for diabetic patients, from whose diet it is considered desirable to exclude starch.

The *acid bread*, so popular in London, is made by a method invented by the English physician Daughish in 1856. According to this method the water used for wetting the dough is directly charged with the requisite amount of carbon dioxide gas and then mixed with the flour in a specially constructed machine. The flour is inclosed in a tight box, moistened with the charged water, thoroughly kneaded by machinery, molded into loaves, and put directly into the oven. The advantages claimed for this form of bread are (1) there is no loss of flour through fermentation, (2) the process is much more rapid, (3) the cost of machinery and gas is less than that of yeast, (4) the process is more sanitary, the bread requiring no handling, (5) the bread is absolutely pure, containing only water, flour, and salt. Sometimes a little fermented barley infusion, or wort, as it is called, from a brewery, is put into the water. This aids it in absorbing the gas, renders the gluten more elastic, and improves the flavor of the bread.

The so-called *salt rising bread* is interesting as an illustration of self-raised bread. In it the ferments originally present or acquired from the air produce the fermentation which leavens it. To make it, warm milk and corn meal are mixed together into a stiff batter, which is left at blood heat until the whole mass is sour, i.e., until the ferments present have produced fermentation throughout. Next a thick sponge is

made of wheat flour and hot water, in which a little salt has been dissolved. This sponge and the sour batter are thoroughly kneaded together and set in a warm place for several hours. The leavening action started in the batter spreads through the dough and produces a light, porous loaf, which many persons consider very palatable. Such bread is quite free from acidity, as the presence of the salt prevents undesirable fermentation.

Various forms of "raised biscuits," "hot bread," etc., are made in the household by adding shortening, milk, eggs, etc., to the dough, or by modifying in some way the process followed. Using soda and cream of tartar, or baking powder, in making biscuits, shortcakes, etc., the process is intrinsically the same as in making ordinary white bread, except that the baking powder or its substitute does the work of the yeast. Such breads do not require to be kneaded or set to rise, and bake very quickly, hence are very convenient when yeast is not obtainable or time is limited. They never become so light and porous as yeast-made bread, however, and dry very quickly.

An interesting variety of bread made without leavening is known as *Maryland* or *beaten* biscuit. A rather stiff dough is made from flour and water, or milk, with shortening and salt added. It is kneaded and then beaten or pounded, being frequently turned over and over until it looks light and puffy. The biscuits are then formed and baked. The folding and pounding of the dough incloses small quantities of air in numberless little blisters. These expand in baking and make the biscuit light and porous. The different kinds of bread from other grains than wheat, as "corn bread," "brown bread," "rye bread," "gems," etc., which are made in many households, vary somewhat in different regions, but they all follow the same principles which govern the bread making from wheat flour, i.e., the flour or meal is mixed to a dough with water or milk, and some leavening substance is generally added to make the dough porous. Eggs, sugar, shortening, etc., may be added, giving rise to the numerous varieties with which we are all familiar.

Digestibility. The digestibility of bread is a very important matter, which has been often studied by methods of artificial digestion and by experiments with man. Among the best known of the latter are those conducted by Meyer and Voit, of Munich. Four kinds of bread were used: (1) rye bread, raised with a leavening powder; (2) bread made from a mixture of rye and wheat flours and raised with yeast; (3) fine white bread raised with yeast, and (4) coarse whole-wheat bread, which the Germans call "pumpernickel," raised with yeast. The third of these—fine white bread—yielded the highest percentage of digestible nutrients; next came the wheat-and-rye bread; then the bread raised with leavening powder, and last, the pumpernickel, which is too coarse to be justly compared with whole-wheat bread such as is made in the United States. The fine white bread was the lightest; next to it stood the rye-and-wheat, and next, that raised with the powder; these breads took the same order with regard to digestibility. These experiments show, not so much the comparative value of different flours, as that the digestibility of bread depends largely upon its lightness.

A number of experiments have been recently made, especially by Snyder, and by Woods and

Merrill, on the digestibility of bread from different grades of flour ground from the same lot of wheat. The average result of a number of such experiments follows:

DIGESTIBILITY OF BREAD FROM DIFFERENT KINDS OF FLOUR

KIND OF FLOUR	Protein	Fat	Carbohydrates	Energy
	%	%	%	%
White bread from standard patent flour	85.3	55.4	97.5	90.1
Entire-wheat flour bread	80.4	55.8	94.1	85.5
Graham bread	77.0	58.0	88.4	80.7

According to the chemical analysis of graham, entire-wheat, and standard patent flours milled from the same lot of hard Scotch Fife spring wheat, the graham flour contained the highest and the patent flour the lowest percentage of total protein. (See WHEAT.) But according to the results of digestion experiments with these flours the proportions of digestible or available protein and available energy in the patent flour were larger than in either the entire-wheat or the graham flour. The lower digestibility of the protein of the latter is due to the fact that in both these flours a considerable portion of this constituent is contained in the coarser particles (bran), and so resists the action of the digestive juices and escapes digestion. Thus, while there actually may be more protein in a given amount of graham or entire-wheat flour than in the same weight of patent flour from the same wheat, the body obtains less of the protein and energy from the coarse flour than it does from the fine, because, although the including of the bran and germ increases the percentage of protein, it decreases its digestibility.

The digestibility of first and second patent flours, as shown by experiments made at the same time as those noted above, was not appreciably different from that of standard patent flour. The degree of digestibility of all of these flours is high, due largely to their mechanical condition, i.e., to the fact that they are finely ground and contain no bran.

Judged by both composition and digestibility, good bread is a wholesome, useful food. As compared with most meats and vegetables, bread has practically no waste and is quite completely digested. It is too poor in protein to be fittingly used alone, but when used with due quantities of other foods, it is invaluable, and well deserves its title of "the staff of life." Statements of a popular nature are frequently met with on the unwholesomeness of hot bread. The fact that bread is hot has doubtless little to do with the matter. New bread, especially that from a large loaf, may be readily compressed into more or less solid masses, and it is possible that such bread would be much less finely masticated than crumbly stale bread, and that therefore it might offer more resistance to the digestive juices of the stomach. However, when such hot bread as rolls, biscuit, or other form in which the crust is very large in proportion to the crumb, is eaten, this objection has much less force. There is little difficulty in masticating the crust, and it is doubtless usually finely divided.

The bran of wheat contains a compound or compounds known as "vitamines," which are

present also in a large number of other food materials and are essential for proper nutrition. It is frequently claimed that because the removal of the bran in milling deprives the flour of this essential ingredient, the finer flours are therefore much less desirable for food than the coarser grades containing the bran. If bread were the chief or only article of the diet, it would be desirable to use the coarser flours, but where a mixed ration of a wide variety of food materials is used, the diet will contain a sufficient amount of the essential ingredient vitamins so that either coarse or fine flour may be used, according to preference.

Imperfections and Impurities in Bread. One of the most common and dangerous faults in bread is heaviness or sogginess. In wheat bread this may be caused by the use of cheap flours, poor in gluten, which cannot absorb all the water put into the dough, or, to state it another way, by the use of too much water in proportion to the flour, by too little or by too poor yeast, or by insufficient kneading, rising, or baking. Heavy bread is popularly considered one of the most indigestible of foods. When chewed, it rolls itself into solid lumps, which give the saliva and gastric juices very little chance to work upon them.

Occasionally the crumb of fresh bread breaks when cut, instead of separating cleanly under the knife. According to Jago, harsh, dry flours, not sufficiently fermented, may be the cause of this, or the dough may have lost its tenacity by being overworked. Another common fault in bread, especially in bakers' bread, is a crumb full of large, irregular holes instead of the small, even pores which it should show. These occur in overkneaded or overraised dough, or if they are found just below the crust they indicate that the oven was too hot and that the crust formed before the carbon dioxide had finished expanding.

Sometimes bread makers are troubled by what is known as "sticky" or "slimy" bread. In such cases bread three or four days old takes on a light-brown color and a peculiar taste and odor. Gradually, too, it becomes sticky or slimy, until it may be pulled into strings, sometimes several feet in length. The trouble appears to be caused by the common potato bacillus (*Bacillus mesentericus vulgaris*), a minute organism which finds its way into the materials of the dough, survives the baking, and, growing in the bread, causes it to decompose.

Recent experiments show that the bacilli enter the bread with the yeast, which in the cases investigated was a variety of the compressed yeasts ordinarily on the market. It was also proved that the bacilli will survive the heat of baking. Accordingly, if yeasts are not carefully made, such trouble may occur at any time, but especially when the weather is warm and favorable to the growth of the bacilli. The best safeguards are to keep the bread in a cool place and to bake only as much as can be consumed within a day or two.

Not infrequently, especially in damp weather, mold forms on the outside, or even in the inside of bread. Mold, like yeast, is a minute plant whose spores (or seeds) are floating about everywhere in the air, ready to settle down and grow wherever they find a moist, suitable material on which to feed. The best practical way to protect bread from them is to keep it in a dry, air-tight box.

But all these faults seem insignificant compared with sour bread. This is due to acetic,

lactic, or, in the worst cases, butyric acid given off by undesirable bacteria, which get into the bread with the yeast or in some other way.

Besides these acid producing bacteria, various others may occur in bread, mostly harmless, but some of them very curious in their effects. Most striking among these is the *Mucococcus prodigiosus*, a minute organism which makes blood red spots in the dough and whose presence gave rise to many interesting superstitions during the Middle Ages.

The adulterants most commonly met with in bread are mineral salts mixed into the dough for the purpose of producing a good looking loaf from poor flour. Alum is the most common of these. Soda is often used in bread to prevent souring, and, as it does not lessen the value, can hardly be called an adulterant. In breads made from special flour, poor in gluten—oatmeal, barley, etc.—soda is regarded as necessary in the production of a sweet, well raised loaf. See also BARLEY, BUCKWHEAT, FLOUR, MAIZE, RICE, etc., WHEAT, ADULTERATION.

BREADFRUIT TREE, *Artocarpus incisa*
A tree of the family Moraceae, a native of the islands of the Pacific Ocean and of the Indian Archipelago. It is one of the most important natural products of these regions, its fruit supplying food, and its inner bark a material for making clothing, while its timber and its milky juice are also employed for economic purposes. The breadfruit tree is a rather slender tree, 40 to 50 feet high, often rising almost half its height without a branch. It has large pinnatifid leaves, frequently 12 to 18 inches long, dark green, and glossy. The fruit is generally oval, or nearly spherical, and about the size of a child's head. It is a sorosis, a compound or aggregate fruit formed from numerous flowers on a common axis, and is covered with a roughish rind, which is marked with small square or lozenge-shaped divisions, having each a small elevation in the centre. It is at first green, when imperfectly ripened, it is brown, and when fully ripe assumes a rich yellow hue. It is attached to the small branches of the tree by a short thick stalk and hangs either singly or in clusters of two or three together. It contains a somewhat fibrous pulp, which, when ripe, becomes juicy and yellow, but has then a rotten taste. At an earlier stage, when the fruit is gathered for use, the pulp is white and mealy and of a consistence resembling that of new bread. In a still less mature state the fruit

contains a viscous white milk. The common practice in the South Sea Islands is to cut each fruit into three or four pieces and take out the core, then to place heated stones in the bottom of a hole dug in the earth, cover them with green leaves, and upon this to place a layer of the fruit, then stones, leaves, and fruit alternately, till the hole is nearly filled, when leaves and earth to the depth of several inches are spread over all. In rather more than half an hour the breadfruit is ready; "the outsides are, in general, nicely browned, and the inner part presents a white or yellowish cellular pulpy substance, in appearance slightly resembling the crumb of a wheaten loaf." It has little taste, but is frequently sweetish and more resembles the plantain than bread made of wheat flour. It is slightly astringent and highly nutritious. Sometimes the inhabitants of a district join to make a prodigious oven—a pit 20 or 30 feet in circumference, the stones in which are heated by wood burned in it, and many hundred breadfruits are thrown in and cooked at once. Baked in this manner, breadfruit will keep good for several weeks. Another mode of preserving it is by subjecting it in heaps to a slight degree of fermentation and beating it into a kind of paste, which, although rather sour, is much used when fresh breadfruit cannot be obtained. There are numerous varieties of breadfruit tree in the South Sea Islands, and they ripen at different seasons, the most highly prized being seedless. The tree produces two, and sometimes three, crops a year. In the West Indies and South America, into which it has also been introduced, the breadfruit has not come much into use as an ordinary article of food, but various preparations of it are reckoned delicacies. The fibrous inner bark of young breadfruit trees, beaten and prepared, is used for making a kind of cloth, which is much worn by the common people in the South Sea Islands, though inferior in softness and whiteness to that made from the paper mulberry. There exudes from the bark of the bread tree, when punctured, a thick, mucilaginous fluid, which hardens by exposure to the air, and is used, when boiled with coconut oil, for making the seams of canoes, pails, etc., water-tight, and as birdlime. The timber is soft and light, of a rich yellow color, and assumes, when exposed to the air, the appearance of mahogany. It is used for canoes, house building, furniture, and many other purposes. It is durable when not exposed to the weather. The jack tree (q.v.) or *jaca* (*Artocarpus integrifolia*), and the daphal (*Artocarpus Lakoocha*), both large East Indian trees, belong to the same genus with the breadfruit tree.

BREAD NUT. The fruit of *Brosimum alicastrum*, a tree of the family Artocarpaceae, and therefore allied to the breadfruit, a native of Jamaica. The genus *Brosimum* is distinguished by male and female flowers on separate trees, in globose catkins. The fruit is a one-seeded drupe. The bread-nut tree abounds in a tenacious, gummy milk which contains rubber. The nuts, boiled or roasted, form an agreeable article of food. Their taste resembles that of hazelnuts.

BREAD-ROOT. See PSORALEA.

BREADTH. The term in art which denotes the quality through which grandeur and simplicity of effect are obtained. In painting, when the play of light upon an object, a group of objects, or a scene, is so managed that the effect is direct and carrying, the work is spoken of as

possessing breadth. Mere outline does not so much contribute to this result as do light and shade and color. It is arrived at often through the suppression of unnecessary detail; still, finish does not preclude, or negligence produce it. Its secret is intelligent vision, and the truthful recording of seen things. Rembrandt in portraiture is a good exemplar of this quality of breadth. Critics of painting often speak of an artist as having a broad touch. This is not close enough to define the meaning of breadth in a large sense, the painter must also possess breadth of vision. Sculpture, too, demands this quality of breadth, and it is achieved in modeling by producing such forms that the light in striking a plastic mass is not so broken by petty forms as to destroy the simplicity and dignity of a figure or group of figures as a monumental whole. The human mind, indeed, is distracted and disturbed, unconsciously, perhaps, in contemplating a so-called work of art in which this quality does not exist.

BREAKBONE FEVER. See DENGUE.

BREAKER. A wave of which the surface is broken, usually by the nearness of the bottom to the water surface. A wave which is of little height in deep water will often increase in height as the depth lessens and finally break into foam. Shoals are invariably covered with breakers in heavy weather, and a very moderate swell will break over rocks or shoals which are only a few feet below the surface. The calls *breakers ahead*, *on the lee bow*, *on the starboard bow*, etc., indicate that breaking waves are seen in the direction indicated, breakers often serve as a warning of a shoal which might be unnoticed in a very smooth sea. Small casks, of oval section, which are used for carrying fresh water in boats, are called *water breakers*.

BREAKERS. See CRUSHING AND PULVERIZING MACHINERY.

BREAKING BULK. A willful breaking open of a package, bundle or box of chattels, and the appropriation of the contents thereof to the uses of the person who breaks it open in such a manner as to amount to a conversion or other violation of the rights of the owner. At common law, a bailee who received goods inclosed in a box or a package was not liable for trespass or theft if he sold the box or package together with its contents; but if he broke open the box or package and sold a part or all of the goods, he was criminally liable. This distinction was based on the theory that the bailor delivered possession of the box or package to the bailee, but not of the goods inside. Hence, when the bailee sold and delivered the box or package there was no wrongful taking from the possession of the bailor but only when he broke open the box or package and disposed of the contents which had not been delivered into his possession. Modern legislation in England and the United States has abolished this distinction, and has declared the fraudulent conversion of the bailor's goods by the bailee to be larceny (q.v.), whether attended by breaking of bulk or not. See BREACH; LARCENY; CONVERSION; SALE; and consult the authorities there referred to.

BREAK-WATER. A barrier of solid construction built out into the open sea or a lake to break the force of the waves and to provide comparatively smooth water inside for the anchorage of vessels or their landing at piers. Some of the great harbor cities of the world, such as New York, Boston, and San Francisco

BREADFRUIT, BANANA, ETC.

4. BREADFRUIT TREE.
5. BANANA (*Musa sapientum*).

in the United States, are on large bays or estuaries so protected by the natural conformation of the land that the heavy waves of the open sea never enter, these are natural harbors, and the cities so located easily reached their important position as ports primarily on account of the ease of access and safety in the anchorage naturally afforded shipping. Other lake or sea-coast cities are situated on open water, but for various economic and geographic reasons have become ports, for these some artificial protection against the force of the waves must be provided.

The use of breakwaters dates back to the earliest days of civilization. The Greeks were proficient in their construction, and they are described in some detail by Vitruvius, the Roman writer on architecture and engineering, and even enter, somewhat ambiguously, into the poetry of Vergil. The earliest use in modern times is the mole or breakwater at Cherbourg, France, which was begun in 1786. In Europe and Asia their use has been somewhat more extensive than in the United States, mainly because the American coast abounds in good natural harbors, but on the Great Lakes of America the design and construction of breakwaters have reached a high development.

The breakwater should be distinguished in its essential elements from the jetty, with which it is often confused. A jetty (qv) is a barrier (generally one of two parallel barriers) built at the mouth of a river in such form as to induce the river currents to scour the bottom of the harbor and remove from the channel there the sand, silt, or earth that is carried down by the river. Breakwaters are intended merely to break the force of the waves, although in occasional instances they serve also as jetties, which accounts for the confusion in terms.

Harbors created by breakwaters are of three classes—those located at the mouth of a river or bay on which is located the city for which the harbor is built, those located on a naturally unprotected shore so that the piers and docks of the port are directly within the breakwater, and harbors of refuge.

This distinction has very little to do with the design of the breakwater, and in fact a number of instances can be cited where the first two types,

at least, are combined. The purposes of the three are, however, somewhat different. A river entering a larger body of water sets up in that larger body a confusion of cross currents very dangerous to navigation, and at the same time the rush of the waves into the funnel-shaped mouth of the river produce there equally dangerous conditions. To reduce these currents and waves to navigable proportions barriers, called breakwaters, are thrown out from either side of the river mouth to within a short distance of one another, leaving an opening through which ships may enter from the rough outer water into a safe inner harbor sufficiently large to take up the effect of the river current and at the same time protected from the outer waves by the breakwater. In some cases these breakwaters serve as jetties. This, however, is, as a rule, a primitive use of the breakwater, for in modern practice the accumulated silt and sand is generally removed by dredging. There is a type of construction sometimes known as a "reaction breakwater," which should more properly be called a "reaction jetty," which is intended to perform the double function of a breakwater and a jetty. It is a single linear structure designed to oppose a portion of the flood tide, and at the same time, from its peculiar curvilinear plan, to produce interfering waves which deposit sand outside of the channel protected and to reflect the ebb tide so as to produce a reaction tending to lower any sand bar across the mouth of the channel.

The second type of breakwater noted above forms a harbor on a generally straight shore line. Within its confines are the usual pier and docks of a port. Its sole purpose is to oppose the force of the waves. A breakwater may shelter a harbor of a different type from either of the two noted above, i.e., a harbor of refuge. This is a roadstead for the temporary anchorage of vessels that need shelter from storms. Such a breakwater is the one at Sandy Bay, Cape Ann, Mass., and the breakwater at the mouth of Delaware Bay, shown in Fig. 6.

The classification of breakwaters given above is according to their purpose. A further classification according to location may be made into connected, detached, and island breakwaters. These are shown in their simplest forms in Fig. 1

FIG. 1. DIAGRAM SHOWING DIFFERENT TYPES OF BREAKWATERS CLASSIFIED ACCORDING TO LOCATION, A, connected, B, detached, C, island

A connected breakwater is one that juts out from the shore, as in *A*, Fig. 1; a detached breakwater one that is entirely disconnected from shore, as in *B*, and an island breakwater one that forms an island of water connected to the mainland by a bridge or viaduct, as in *C*. The first and second are quite similar in design, peculiarities in sea-floor contour and land topography governing the selection. The island harbor, however, has been built in only rare instances because the difficulties in construction and its inaccessibility to shore outweigh the advantages of a smooth harbor which can be built with a minimum of material and removed from the sediment-bearing waves of the shore line.

The design of breakwaters is largely empirical, based on the behavior of certain types of construction in the past. The structures have to be built in the open sea, in peculiarly exposed positions subject to the enormous force of the ocean or lake waves. The stresses to which they are subjected are therefore not susceptible of mathematical analysis except in the most general way. The three factors to be decided upon in any breakwater are the location, the type of structure, and the size of section. As to location, a breakwater is so placed as to afford the maximum protection to the type of shipping which the harbor draws, and this location depends upon the channel, the prevailing winds, and the depth of water. The types of structure are numerous; they are discussed below. The dimensions of the section are governed by the prevailing height, length, and force of the waves, all of which depend upon the fetch (the length of open sea outside the breakwater), the depth of water, and the character of the bottom. The height also varies with the amount of protection required immediately inside the breakwater. Thus, in a harbor of refuge, where the vessels may anchor far back from the breakwater, a certain amount of water breaking over the barrier is of minor importance. In a small fishing harbor, on the contrary, the vessels often tie up immediately alongside the breakwater, in which case breaking waves are undesirable.

The determination of wave condition is largely empirical, being based on observed conditions in the harbor in question or in similarly disposed harbors. An approximate value may be obtained by the application of mathematical formulas, the most important of which is that devised by Mr. Thomas Stevenson, the famous English engineer of the last century. This formula is that the height of waves, in feet, from crest to trough is equal to one and one-half times the square root of the "fetch" in nautical miles, where the conditions are favorable with regard to depth for wave development, and the time during which the storm lasts is sufficient for the production of waves of maximum force.

In regard to the force and height of waves, it is recorded that at Peterhead Breakwater, England, in a storm in 1808, blocks weighing upward of 41 tons were displaced at a level of 36 feet 7 inches below low water. It was computed that this required a wave force of fully 2 tons per square foot. At Colombo, Island of Ceylon, a length of wall 24 feet wide, founded 20 feet below low water (tide rise, 2 feet), was canted inward to an extent of 15 inches over 150 feet of length. At the Bishop Rock Lighthouse, Scilly Isles, after a gale, sand from a bottom 150 feet deep was found on a gallery 120 feet above the water. These are a few

instances of what the masses of stone must withstand under extreme conditions. Pressures due to impact of high waves have been measured by dynamometers. For waves 10 feet high, pressures of 1800 to 3000 pounds per square foot have been observed, while for 25-foot and 30-foot waves the pressures have risen as high as 7000 pounds per square foot.

The profile of the breakwater section has varied from the rectangular timber crib to the approximately circular surface (see Fig. 5), in the effort to produce the greatest obstruction to the waves with the least destructive effect upon the structure. No pronounced standard of section has been generally accepted in practice, although it is admitted that the sloping face on the sea side is preferable. The various structures shown in the accompanying cuts illustrate the trend of profile design. The following conclusions as to shape, by Col. D. D. Gaillard, U. S. A., are representative of current engineering opinion. (a) A sloping-face breakwater with vertical back wall, located in water less than 30 feet deep, will afford sufficient protection to the area in the rear, provided its height above water during storms is not less than two-thirds the height of the greatest waves that assail it; (b) unless the height and top width of the breakwater are unduly great, so much water will pass over the top during severe storms that it would wash completely over the decks of vessels alongside the breakwater. (c) Both the vertical and sloping-face breakwaters will reflect waves, provided the height is sufficient, even although the angle of slope with the horizontal is as small as 23°.

The different types of breakwater construction may be classified as (a) timber crib; (b) timber crib with masonry deck; (c) rubble mound; (d) stone or concrete block and mass concrete; (e) hollow concrete crib. These will be briefly described, with examples of each.

The timber-crib type is the simplest form of breakwater, used now only in minor harbors or under primitive conditions. It was the type universally adopted for the first breakwaters on the Great Lakes, where the lack of natural harbors early required artificial protection. It consists essentially of a series of timber cribs, made up on shore of hewn logs and floated into place above a prepared footing, onto which they were sunk by filling with riprap stone. These cribs were generally built from 30 to 35 feet square, divided into compartments by transverse and longitudinal walls, the cribs being sunk side by side along the line of the proposed breakwater. On top of these filled cribs was built a continuous timber superstructure, generally carried up to a height of about 7 feet above lake level and then decked over. For heavy-sea work the form of the superstructure was changed so as to make the outer part or parapet about 12 feet high and the inner part, or banquette, about 5 feet. Fig. 2 shows a section through the breakwater at Presque Isle, Mich., typical of this type.

These timber breakwaters had the advantages of simplicity in construction and cheapness and availability of material, but they had a very short life. The above water timber soon decayed, and the cribs were easily damaged and destroyed by sand and ice erosion and by the wedgelike action of the small stone filling moved by the force of the waves. Their average life was about 15 years.

An improved modification of this type was made in the East breakwater at Cleveland, Ohio. This was carried up vertically for only 2 feet above water level and was then inclined at an angle of 1 on 2.5 until it attained a height of 10 feet above the water surface on the lake side.

FIG 2 PRESQUE ISLE BREAKWATER, LAKE SUPERIOR

From that point it was horizontal until it met the harbor face, which was vertical. All the decking was made of 12-inch timbers instead of planks, and iron straps were added on the lake-side lower edge to prevent too rapid erosion there. This sloping and smooth face presented a surface up which the storm water slid with much less damage to the structure than in the original crib structures, and the general shape has been adopted for the masonry types noted below.

The next improvement on the Great Lakes

FIG 3 CLEVELAND (OHIO) BREAKWATER, LAKE ERIE

was the composite breakwater, first used at Oswego, N. Y. This consisted in substituting a superstructure of cut stone laid up in cement mortar for the former timber superstructure. It was found, however, that the foundation afforded by the comparatively flexible timber cribs was so poor that the cut-stone masonry was soon shaken to pieces. The substitution of

a solid concrete superstructure was then attempted and was found more stable, and this has been adopted in a number of ports, notably at Cleveland and Buffalo. In preparing this type the cribs are cut off about 3 feet below mean water, and concrete blocks about 4 feet wide,

FIG 4 A SIMPLE RUBBLE MOUND BREAKWATER. A CLEVELAND BREAKWATER

4 feet high, and 8 feet long are prepared and placed upon the top of the walls of the crib. The small stone filling is then carried up to within a few inches of the top of the blocks, and upon this the surface of mass concrete is molded in place across the full width of the crib. In the Cleveland breakwater, shown in Fig 3, the mass concrete of the banquette is 5 feet thick, the parapet 5 feet high, and the concrete mass blocks alternately 20 and 30 feet long, separated by a tar-paper joint. This type is much more stable than the ones previously described, but there is still a movement of the superstructure, and in most cases the further protection of riprapping is required. In the later developments of these types they are not founded on the bottom, but on sloping mounds

FIG 5 PLYMOUTH (MICH) BREAKWATER

of riprap dumped into place, or on piles, thus insuring a more stable foundation against the undermining force of the waves.

A radical change from the timber-founded types is the rubble mound breakwater, which is the one most generally used in the exposed locations where wave force is very great. This consists essentially in first building up, by dumping from trestles or barges, a mound of small stone to somewhat below water level, and then dumping upon this at random large blocks of stone so that the whole forms a generally trapezoidal section. There are many variations of this type, but the section in Fig 4 of another of the Cleveland breakwaters will serve to illustrate the general design. The advantages of the

FIG 6 NEW DELAWARE BREAKWATER

type are that they are comparatively simple to build, and that any repairs consist merely in dumping more stone on top of the mound to replace that forced over on the slopes by the waves. In time the mound will take a permanent section, and repairs are slight. The main

disadvantage is the great amount of stone that has to be used, and the comparative roughness of the inner harbor due to lack of sufficient barrier above water.

To avoid this latter difficulty, the block breakwater is used. In this type a superstructure of out stone or mass concrete is placed on the under-water riprap structure. These upper stones may be placed in different fashion, as is illustrated in Figs. 5 and 6, which show the

FIG. 7. A CONCRETE-BLOCK BREAKWATER, HARBOR BEACH, MICH.

block breakwaters at Plymouth, England, and at the mouth of Delaware Bay. Occasionally the improvement consists merely in paving the sea face of the breakwater with large stone blocks.

An improvement of the masonry type is the use of concrete blocks instead of stone. These blocks are cast on shore and are placed with precision on the rubble mound. Their advantage lies in the ability to easily make bonds in the blocks so that they may be tied together in the superstructure as a solid mass. Illustrations of the type are shown in Fig. 7.

FIG. 8. A SOLID CONCRETE BREAKWATER, ABERDEEN, SCOTLAND.

Another variation is the use of a solid concrete superstructure cast in place in the breakwater, either on pile footings or on a rubble mound. The disadvantage of the block type is the high cost; the main advantage the relative permanence of the construction.

The latest type of concrete breakwaters are those made of hollow concrete cribs, molded on shore, floated to place in the line of the breakwater, there to be sunk by filling with riprap, and decked with a continuous concrete decking. This, it will be observed, is precisely the same principle as that used in the primitive timber cribs, except that the more durable concrete is substituted for wood. Their principal application to American practice has been at Algoma

STATISTICS OF NOTABLE BREAKWATERS

Location	Style of breakwater	Greatest continuous length Ft.	Depth at low water Ft.	Total height Ft.	Width of base Ft.	Width of top Ft.	Cost per Ft. \$	Total cost of construction \$

Harbor, Wis A cross-section of this is shown in Fig 9

It should be stated that there are many technical problems connected with the design of breakwaters which cannot be entered into here, but for information concerning which the authorities at the end of this article should be

FIG 9 A CONCRETE-CRIB BREAKWATER, ALGOMA, WIS

consulted. These problems relate mainly to the shape of the cross-section, the location of the breakwaters, the proportion and location of the different sizes of stone in the rubble and block types, and the precise effect of the wave force on the structure. The accompanying table, taken from one prepared by Gen Theodore L Bingham, U S A, when he was in active service in the Corps of Engineers, gives data on some of the large breakwaters of the world.

Bibliography No one book contains very recent or complete information on breakwaters. The best data are available in the reports of the Chief of Engineers, U S A, the *Proceedings of the American Society of Civil Engineers*, the *Minutes of Proceedings of the Institution of Civil Engineers*, *Engineering News* (New York), *Engineering Record* (New York), *Engineering* (London), and *Engineer* (London), all current. In addition the following books may be consulted: Vernon-Harcourt, *Harbors and Docks* (London, 1885), Cunningham, *Harbor Engineering* (London, 1908), De Caidmog, *Les ports modernes* (Paris, 1900), Schulze, *Seehafenbau* (Berlin, 1911-13). See HARBOR, JETTY

BRÉAL, bré'AL, MICHEL JULES ALFRED (1832-) An eminent French philologist, born at Landau (Rhenish Bavaria), of French parents. He was educated at Weissenburg, Metz, the Lycée Louis-le-Grand (Paris), and Berlin, where he studied under Bopp. In 1864 he was appointed professor of comparative grammar at the Collège de France, in 1875 was elected to the Academy of Inscriptions and Belles-Lettres, and from 1879 to 1888 was an inspector general of higher education. In 1890 he was elected commander of the Legion of Honor. His publications include *L'étude des origines de la religion Zoroastrienne* (1862),

which obtained the prize of the Academy of Inscriptions, *Le mythe d'Œdipe* (1864), a valuable translation of Bopp's *Vergleichende Grammatik*, with learned historical and critical introductions (5 vols, 1866-74), with A Bailly, a *Dictionnaire étymologique latin* (1885, 5th ed, 1902), *Pour mieux connaître Homère* (1906), *Deux études sur Goethe* (1898). Bréal is generally considered the founder of the modern science of semantics or semiology. At least, his *Essai de sémantique* *Science des significations* (Paris, 1897, 3d ed, 1904) was the first work to treat systematically and scientifically the development of meaning of words. An English translation was made by Mrs Cust (London, 1900), with a preface by Postgate.

BREAM (ME *bream*, OF *brasme*, OHG *bralsuna*, *bralsuna*, *bream*) A name applied to a variety of fishes belonging to different families. The common English bream, or carp bream (*Abramis brama*), is a member of the Cyprinidae family, and an inhabitant of many rivers and lakes of Europe, even as far north as Norway and Sweden, and of some of those of England and Ireland. It thrives best in still water, and many grow to a weight of 6 to 12 pounds. The white bream (*Abramis albus*) differs from the common bream in its silvery color, in its smaller size, and in several structural details. It also occurs on the Continent and in England. These fishes are favorite objects for quiet angling in England, and the carp bream was descanted upon at a great length by Isaac Walton. In America a minnow, the golden shiner (*A. chrysoleucus*), and a sunfish, the pumpkin seed (*Eupomotis gibbosus*), are commonly called "breams" in the Eastern States. (See MINNOW, SUNFISH.) Several species of porgies (*Sparidae*) also receive the name. See PLATES OF CARPS AND ALLIES, and DARTERS AND SUNFISH.

BREAST (AS *brōst*, Goth *brusts*, Ger *Brust*, so called from its swelling protuberances, cf AS *berstam*, Eng *bust*). One of the two lacteal glands situated on a woman's chest. The male also possesses mammary glands and nipples but in a rudimentary form. A breast consists of a series of tubes, radiating from a common center, the nipple, which is situated in an areola, a pink or dark-colored, nearly circular, area. On the surface of the latter are from 4 to 10 sebaceous glands, which secrete an oily fluid to protect the skin of the nipple, which is very thin, from the saliva of the sucking infant. The milk tubes (15 or 18 in number) enlarge into sinuses and pass each to a separate lobe or subdivision of the breast, where they divide into twigs and branches (the *lactiferous ducts*), which end in minute vesicles. The lobes are held together by fibrous tissue, and are well packed in fat, which increases sometimes to an enormous extent the apparent size of the organ. It will be readily understood how overdistention of these delicate tubes, from whatever cause, must be productive of great suffering. Such a condition often arises during the nursing period, from overactivity of the gland combined with deficient emptying, and is known as "caked breast." This may progress to inflammation (mastitis) or abscess formation. When an abscess forms in the breast it is dangerous to allow the pus to remain, and when an opening is made into the abscess the incision should radiate from the nipple, so as to avoid division of the milk tubes. Besides in-

inflammatory affections, the female breast is also subject to tumors. See TUMORS.

BREASTBONE. See STERNUM.

BREASTED, JAMES HENRY (1865-). An American Orientalist, born at Rockford, Ill., and educated at Northwestern College, Chicago Theological Seminary, and Yale. For a number of years he was connected with the departments of Egyptology and Semitic languages at the University of Chicago, and in 1905 was appointed professor of Egyptology and Oriental history; he also became director of the Haskell Oriental Museum of the University of Chicago in 1901. One year (1900) he spent, by commission of the four royal academies of Germany, in copying and arranging the Egyptian inscriptions possessed by the museums of Europe; these were then to be used in preparing the Egyptian dictionary. In 1905-07 he was director of the University of Chicago Egyptian expedition. Besides acting as associate editor of the *American Journal of Semitic Languages* and of the *Biblical World*, and contributing to various foreign scientific journals, he wrote: *A New Chapter in the Life of Thutmose III* (1900); *Ancient Records of Egypt* (5 vols., 1905); *A History of Egypt* (1905; 2d ed., 1909); *The Temples of Lower Nubia* (1906); *A History of the Ancient Egyptians* (1908); *The Monuments of Sudanese Nubia* (1908).

BREAST-PLATE. In ancient and mediæval armor, a plate of iron, steel, or other metal worn to protect the breast. At the end of the twelfth century the breastplate made its appearance in mediæval armor, as a thin plate of iron worn under the gambeson (q.v.). The custom of wearing it above the other defensive armor began in the thirteenth century and was developed in the fourteenth. The backplate, in like manner, was worn as a protection for the back. In modern armies the breastplate is represented by the front half of the cuirass worn by the cuirassiers in continental armies and by the Life Guards and Horse Guards in England.

BREAST-SUMMER, or BRES-SUMMER. A beam or "summer" (q.v.) supporting the whole front of a building, in the same way in which a lintel supports the portion over an opening. They are seen in England and on the continent of Europe, in old houses built partly of wood and partly of stone, brick, or mud.

BREAST WHEEL. See WATER WHEEL.

BREAST-WORK. See FORTIFICATION, and TRENCH.

BREATH (AS. *brath*, odor, smell, exhalation, OHG. *brâdm*, Ger. *brodem*, vapor, steam, exhalation), **OFFENSIVE.** The foul odor of breath may be due to a variety of causes, the most important being as follows: 1. *Digestive disturbance with constipation.* A purge should be used, repeating till the tongue is clean. Indigestible food, as well as beer and distilled liquors, should be avoided, especially if gas be produced in the stomach. 2. *Carious teeth.* 3. *Food fermenting in the mouth.* All cavities should be filled. Food should be picked from between the teeth carefully after each meal and the mouth thoroughly rinsed. The teeth should be brushed morning and evening. 4. *Catarrh of nose,* especially the disease called "ozena," which gives rise to a penetrating and offensive odor, due to the activities of a specific bacillus; warm nasal douches will help this condition, but treatment should be intrusted to a physician. Adenoid vegetations, especially in children, some-

times give rise to foul breath; and chronically diseased tonsils frequently harbor in their crypts small masses of fetid material which has the same effect. Dead bone or dead cartilage (generally the result of syphilis) in the nasal cavity causes a most offensive odor, and removal is the only treatment. Abscess in the socket of a tooth or in the soft tissues of the mouth must be relieved by a dentist or surgeon. 5. An intensely fetid breath is characteristic of gangrene of the lungs, fetid bronchitis, bronchiectasis, pulmonary actinomycosis, old abscesses of the lungs, and the various forms of stomatitis. Certain diseases produce an odor of the breath peculiar to themselves. Uremia gives an ammoniacal odor to the breath; *diabetes mellitus* gives rise to a heavy sweetish odor; cancer of the stomach, intestines, or of the air passages produces a foul-smelling breath, as does diphtheria. In children intestinal worms are a cause.

Many drugs communicate their odor to the breath. Familiar examples are ether, chloroform, tobacco, and alcohol. The heavy narcotic smell of opium, the garlicky odor of phosphorus poisoning, and the smell of peach kernels in hydrocyanic acid poisoning are well known to physicians.

BREATH'ING. See RESPIRATION.

BREBEUF, brâ'bêf, JEAN DE (1593-1640). A Jesuit missionary. He was born at Bayeux, northern France, March 25, 1593, and was killed in the Huron country, March 10, 1640. He came to America with Champlain in 1626, and his labors were mainly among the Hurons, with whose life and language he was very familiar. When the town of St. Louis was taken by the Iroquois, Brebeuf and Lalemont, his associate, were made prisoners and tortured to death. It is said that Brebeuf's skull is preserved in the pediment of a silver bust in the convent of the hospital nuns in Montreal. Some of his writings on the Huron language are preserved, and were translated by Albert Gallatin and published in the *Memoirs of the American Antiquarian Society*, and some of his letters by Carayon (Paris, 1870). Consult his account in the *Jesuits' Relations*, ed. Thwaites (Cleveland, 1896-1901). Consult also Parkman, *Jesuits in North America* (Boston, 1835).

BRECCIA, brê'châ (It. fragments of stone; cf. Fr. *brèche*, Eng. *breach* and *break*). In petrography, a mass composed of angular fragments of rocks cemented by mineral material. The angular fragments may consist of any kind of rock, such as sandstone, limestone, granite, or gneiss, or, as sometimes happens, of a mixture of different kinds. The cementing material is commonly quartz, calcite, iron oxide, or a clayey substance. A breccia may be formed in a number of ways: (1) in the same way as a conglomerate (q.v.), except that the fragments are not rounded by water; (2) by the breaking of a rock into angular fragments by dynamic action, with subsequent cementation; (3) angular blocks may be thrown from volcanoes, which, after falling, become consolidated; (4) the surface of a lava flow may harden, break into angular fragments, and be engulfed in the soft magma beneath, which on cooling yields a breccia; (5) in the intrusion of igneous rocks (q.v.), angular fragments broken from the walls may be caught in the molten mass of the intruded material; (6) some breccias have been formed by cementation of the loose angular frag-

ments of talus slopes or scree See EROSION, TALUS

BRÈCHE DE ROLAND, bièsh de rô'lan' (Fr Roland's Breach). A defile in the Pyrenees forming a passage between France and Spain, at the Crique de Gavarnie, a few miles west of Mont Peidu. According to the legend, Roland made the cleft in the rock with his sword Durandal in the fight at Roncesvalles. The pass is about 200 feet wide and has an elevation of 9000 feet.

BRECHIN, brêch'n A town of Pforzshire, Scotland, on the South Esk, $7\frac{1}{4}$ miles west of its junction with the sea at Montrose (Map Scotland, F 3). Its chief architectural feature is a massive round tower of a character frequently met with in Ireland, but quite uncommon in Scotland. It is 86 feet high, and 16 feet in diameter at the base, and surmounted by a hexagonal spire 18 feet high which was added in the eighteenth century. It was built about 1000. The town is well lighted and has an excellent water supply. The chief industries are spinning, bleaching, and the manufacture of linens and sailcloth. Pop., parliamentary and municipal burgh, 1901, 8941, 1911, 8439. Brechin was once a walled town. David I founded a cathedral and bishopric here in 1150. The town was burned by Montrose in 1645. Consult *Registrum Episcopatus Brechensis* (2 vols., Aberdeen, 1850).

BRECK, JAMES LLOYD (1818-76) An American clergyman and educator. He was born in Philadelphia, graduated at the University of Pennsylvania in 1838, at the General Theological Seminary in 1841, and in the latter year joined a mission for work among the Indians in Wisconsin. Later he established the Protestant Episcopal church schools at Faribault, Minn., and was engaged in organizing similar schools at Benicia, Cal., when he died.

BRECK, SAMUEL (1834-) An American soldier, born at Middleborough, Mass. He graduated in 1855 at the United States Military Academy, served as lieutenant of artillery in the Seminole War, and from 1860 to 1861 was assistant professor of geography, history, and ethics at the Military Academy. During the Civil War he was assistant adjutant general successively of General McDowell's division, the First Army Corps, and the Department of the Rappahannock, and assistant in the adjutant general's office at Washington. Brevetted brigadier general, U S A., he continued in the adjutant general's department until retired in 1898, and attained the rank of brigadier general and adjutant general.

BRECKENRIDGE A city and the county seat of Wilkin Co., Minn., 215 miles west by north of St. Paul, on the Red River of the North, the Otter Tail, and the Bois de Sioux rivers, and on the Northern Pacific and the Great Northern railroads (Map Minnesota, A 4). It is a railway division point and has grain elevators, flour mills, etc. Breckenridge contains a hospital and owns its water works and electric light plant. It has adopted the commission form of government. Pop., 1890, 655, 1900, 1282, 1910, 1840.

BRECKENRIDGE, HUGH HENRY (1870-). An American painter, born at Leesbury, Pa. He was a pupil at the Pennsylvania Academy of Fine Arts and won the scholarship for study abroad (1892). He then studied with Bouguereau, Ferner, and Doucet in Paris. On

his return he became instructor and secretary of the Faculty of the Pennsylvania Academy in 1894. His paintings, both oil and water color, are praised for the facility of their execution. He received the Corcoran prize at Washington in 1903 and the gold medal of the Philadelphia Art Club (1907), and was on the International Jury of Awards at the St. Louis Exposition in 1904. He is represented in the collections of the Pennsylvania Water Color Club, and the Art Club of Philadelphia, the St. Louis Club, and the University Club of Indianapolis.

BRECKENRIDGE, LESTER PAIGE (1858-) An American mechanical engineer, born at Meriden, Conn. He was educated at the Sheffield Scientific School of Yale University, became instructor at Lehigh University in 1882, was professor of mechanical engineering at the Michigan Agricultural College in 1891-93, and a professor at the University of Illinois in 1893-99. The last-named institution's Engineering Experiment Station he directed from 1905 until 1909, when he became professor of mechanical engineering at the Sheffield Scientific School. In 1897-99 he designed the dynamometer car, and in 1901 he invented an automatic recording machine. His publications include *An Extension of the Dewey Decimal System of Classification Applied to the Engineering Industries* (1899, 6th ed., 1912), *High Speed Tool Steels* (1905), *Fuel Tests with Illinois Coal* (1908), *Steaming Tests of Coals and Related Industries* (1912).

BRECKINRIDGE, JOHN (1797-1841) An American clergyman, born in Cabell's Dale, Ky. He graduated at Princeton College (1818) and studied at the Theological Seminary, and in 1822 was licensed by the Presbyterian church to preach. He was chaplain of the Federal House of Representatives from 1819 to 1821. His first church was in Lexington, Ky. (1823-26), where he established a newspaper, the *Western Luminary*. He also had a charge in Baltimore from 1820 to 1831, when he removed to Philadelphia and for several years was secretary and general agent of the Presbyterian Board of Education. In 1836 he became professor of theology in Princeton Theological Seminary, and two years later he was made secretary and general agent of the Board of Foreign Missions. He resigned in 1840 and just before his death was chosen president of Oglethorpe University, in Georgia. He published, under the title *Roman Catholic Controversy* (1836), his famous debate with the Rev. John Hughes, afterward Archbishop of New York.

BRECKINRIDGE, JOHN CABELL (1821-75) An American lawyer, soldier, and politician, born near Lexington, Ky. He was educated at Centre College and at Transylvania University and practiced law at Lexington. He served as major in the Mexican War, sat in the State Legislature, and was a member of Congress from 1851 to 1855. In 1856 he was elected Vice President of the United States on the ticket with James Buchanan. In 1860 he was nominated for President by the extreme Southern section of the Democratic party, but, with Douglas and Bell, was defeated by Lincoln, receiving 72 electoral votes. He was immediately chosen United States Senator, but resigned to join the Secessionists, and entered the Confederate army. He was made a major general in 1862, served throughout the war, and took a prominent part in the battles of Shiloh, Murfreesboro, Chicka-

mauga, Chattanooga, and Cold Harbor. He was Early's second in command in the Shenandoah campaign in 1864. From January to April, 1865, he was Secretary of War in the cabinet of Jefferson Davis. At the close of the conflict he escaped to Europe, where he remained until 1868, after which he devoted himself to the practice of law.

BRECKINRIDGE, JOSEPH CABELL (1842-). An American soldier, born in Baltimore, Md., a son of Robert J. Breckinridge. He studied at Centre College, Ky., and the University of Virginia, entered General Nelson's army of Kentuckians, and subsequently was assigned to the Second Artillery, U. S. A. He served in the Shiloh, Gulf, and Atlanta campaigns, and was brevetted major for meritorious conduct before Atlanta. He was a member of the staffs of Generals Thomas, McDowell, and Halleck. He became brigadier general and inspector general in 1889. During the Spanish-American War he served as major general of volunteers in the Santiago campaign. He was inspector general of the United States army from 1899 until he retired in 1903.

BRECKINRIDGE, ROBERT JEFFERSON (1800-71). An American clergyman, brother of Rev. John Breckinridge (q.v.). He was born in Kentucky, graduated at Union College in 1819, practiced law in his native State, and was a member of the Legislature. In 1829 he joined the Presbyterian church, and in 1832 obtained a charge in Baltimore, where he remained for 13 years. In 1845 he became president of Jefferson College, and two years later removed to Kentucky and became State Superintendent of Public Instruction. In 1853 he became professor of theology in Danville Seminary. He was a strong old-school leader in the great division of the Presbyterian church. In the slavery discussion he was extreme on neither side, and when the Civil War began he was for the Union, though he was much opposed to the Emancipation Proclamation (q.v.). In 1864 he was president of the Republican convention which nominated Lincoln for a second term. Dr. Breckinridge is credited with having been the principal author of the common-school system of Kentucky. His principal work is *The Knowledge of God, Objectively and Subjectively Considered* (2 vols., 1857-59).

BREC'ON, or BRECK'NOCK (from *Brychan*, a native prince of the fifth century), or **ABERONDDIRU**. The capital of Brecknockshire, South Wales, situated in an open valley in the middle of the county, at the confluence of the Usk and Honddlu, 171 miles west-northwest of London (Map: Wales, C 5). It lies in the midst of fine mountain scenery and has beautiful public walks. The Priory of St. John is an excellent example of early English architecture and is considered the finest parish church in Wales. Ely Tower, the only remaining fragment of the old castle, is famous as the scene of the conference between the Bishop of Ely and the Duke of Buckingham, which resulted in the overthrow of Richard III. The town owns its water supply, markets, and slaughterhouses. It has manufactures of flannel and coarse cloth, but its principal trade is in lime. Pop., 1891, 5794; 1901, 5875; 1911, 5908. South of Brecon lie the twin mountain peaks, the Brecon Beacons. The town was founded soon after the Conquest. It was the birthplace of the famous actress Mrs. Siddons.

BREC'ONSHIRE, or BRECK'NOCKSHIRE.

An inland county of South Wales, to the south of Radnor, from which it is separated by the Wye. Its length is about 35 miles, its average breadth 20 miles, and its area 734 square miles, of which two-thirds are cultivated (Map: Wales, C 5). Coal, iron, and lead are mined, and there are important iron manufactures, but agriculture provides the chief industries. The chief towns are Brecon, the county town and the only corporate one, Builth, Cricheffell, Hay, and Llanelli. Pop. (half of whom speak Welsh), 1891, 57,000, 1901, 59,900. 1911, 65,999.

BREDA, brá-dá' (Dutch *brede*, a plain, from *breed*, A.S. *brād*, Ger. *breit*, Eng. *broad*). A town in the province of North Brabant, Holland, situated at the confluence of the Merck and the Aa (Map: Netherlands, C 3). It has an old castle, dating from 1350, which was for a time the residence of Charles II of England, but is now used as a military academy. Among the numerous churches, the most prominent is the Gothic cathedral dating from the fifteenth century, and containing the magnificent tombs of Count Engelbert II of Nassau and his wife. The fortifications of the town, now dismantled, were once very formidable and were provided with facilities for inundating the surrounding country in case of war. Breda manufactures carpets, cloth, and cigars, and its commerce is facilitated by a good harbor. The town has had a very stormy career and has been the scene of a number of historical events. It was besieged and taken repeatedly by the Spanish and the French, and it was at Breda that the protest of the Dutch nobles against Spain, known as the "Compromise of Breda," was presented in 1566. It was also from Breda that Charles II issued his "declaration" before his restoration in 1600. Pop., 1905, 27,503; 1911, 27,259.

BREDA, DECLARATION OF. See CHARLES II. **BREDAHL**, brá-dál', CHRISTIAN HVIID (1784-1860). A Danish poet. He was born at Hellestrup and was a fellow pupil of Ingemann at the gymnasium of Slagelse. His first poetic work, *Dramatiske Scener*, was published in 5 vols. from 1819 to 1835. In these dramas, as in his later works, he reveals an intense love of natural conditions and a thorough dislike of excess of culture. Bredahl is closely identified with the philosophical spirit of the eighteenth century as exemplified by Rousseau; and in his masterpiece he inveighs against tyranny and avarice, the arrogance of the nobility, and the domination of the priesthood. He died in penury. A new edition of his *Dramatiske Scener* was published in 1885 in 3 vols. at Copenhagen.

BREDEN, brá'den, CHRISTIANE (1844-1901). An Austrian actress and poet known under the pseudonym of Ada Christen, born as Christiana Friderik in Vienna. She was married in 1864 to Siegmund von Neupauer and in 1873 to Adalmar Breden, but retained her pseudonym. She was at first an imitator of Heine, but developed considerable originality in her later works. Her works include *Lieder einer Verlorenen*, poems (1868; 3d ed. 1873); *Schatten*, poems (1873); *Faustina*, a drama (1871); *Emma*, a novel (1873); *Unsere Nachbarn* (1884); *Jungfer Mutter, eine Wiener Vorstadtschichte* (1892).

BREDERO, brá-dá'ró, GERBRAND ADRIAENSZON (1585-1618). A Dutch playwright and poet, born in Amsterdam. He was educated as a painter, but turned to literature, in which he

became celebrated for his lyrics (4th ed, Amsterdam, 1622), and took rank among the foremost Dutch writers of comedy. His most important plays are *Het Moortje* (1615), *De Stomme Riddet* (1618), and *Spaansche Babanders Verolimo* (1618). The last named is considered his best work. His *Works* were first published in Amsterdam in 1638, the last edition was that of 1885-88 (1b, 3 vols.) Consult the study by Ten Brink, *Gerhard Adriaenszoon Brederode* (Utrecht, 1859).

BREDERODE, brâ'de-rô'de, HENDRIK, COUNT VAN (1531-68). One of the sovereign counts of Holland, and a leader against Spanish domination in that country. He was one of the leaders of the League of the Gueux ("The Beggars"), and is said to have drawn up the "Compromise" of 1566. After the complete success of the Spaniards he asked Egmont to intercede for him with the regent. His followers, however, were dispersed, some were put to death, and he himself died a few months later in Germany, whither he had fled.

BREDOW, brâ'dô, ADALBERT VON (1814-90). A German soldier, born in Berlin. As commander of the Second Cavalry Brigade of Prussia, during the War of 1866, he rendered distinguished services at the battles of Trautenau and Sudowa. Upon the outbreak of the Franco-Prussian War he was assigned to the command of the Fifth Cavalry Division, in which capacity he performed, with barely six squadrons, the most brilliant cavalry charge of the war—the desperate assault at Mars-la-Tour, by means of which a large division of the French army was rendered powerless to assume the offensive. The gallant feat of this officer, who became lieutenant general in 1871, has been perpetuated in song and story.

BREDOW, GOTTFRIED GABRIEL (1773-1814). A German historical writer, born in Berlin. He studied at Halle, in particular classical subjects under F. A. Wolf, succeeded J. H. Voss as rector of the school at Eutin (Lubeck) in 1802, and in 1804 became professor of history in the University of Helmstedt. In 1809 he was appointed professor in the University of Frankfurt-on-the-Oder, with which he continued to be connected after its removal to Breslau, in 1811. His publications include a *Handbuch der alten Geschichte*, (*Geographie und Chronologie*) (1799, 6th ed 1837), *Untersuchungen über einzelne Gegenstände der alten Geschichte*, (*Geographie und Chronologie*) (1800-02), *Chronik des neunzehnten Jahrhunderts* (2 vols, 1804-05, continued by Venturini), highly esteemed by Germans of the time because of its bold expressions regarding French domination. His *Weltgeschichte in Tabellen* (1801, 9th ed 1851) was translated (with additions) into English by J. Bell (London, one vol folio, 1820, from the 4th German ed.), and his *Merkwürdige Begebenheiten aus der Allgemeinen Weltgeschichte* reached its thirty-seventh edition in 1880.

BREE, brâ, MATTHEU IGNACE VAN (1773-1839). A Flemish historical and portrait painter. He was born in Antwerp and studied at the Academy in that city and under P. J. van Regemorter, also in Paris under Vincent. He was appointed professor at the Academy of Antwerp in 1804 and director in 1827. His art was in the customary classic manner of his day, modified by the influence of Rubens. He played a more important part as a teacher than as a painter, and among the men whom he

helped to train were Wappers, De Keyser, De Baekelaer, Van Ysendyck, and Wiertz.

BREECH (*breach*, the hinder part of the body, AS *briça*, breeches, pl of *briça*, Dutch *broek*, a pair of breeches, cf Lat *braccæ*, trousers, breeches.) The rear part of a gun or other object. The heavy piece of metal which closes the breech of a gun and receives the pressure of the powder gas is known as the *breechblock* or *breech plug*. When a gun is charged through the breech, it is known as a breechloader. The breech and its adjuncts are important parts of guns and small arms and will be found described and illustrated in the articles GUNS, NAVAL, ORDNANCE, SMALL ARMS.

BREECHES BIBLE See BIBLE, CURIOUS EDITIONS OF.

BREECHES BUOY See LIFE-SAVING SERVICE.

BREECH-LOADING ARMS See SMALL ARMS, ARTILLERY, COAST ARTILLERY, FIELD ARTILLERY, GUNS, NAVAL, ORDNANCE.

BREED, DAVID RIDDLE (1848-) An American Presbyterian clergyman and educator, born in Pittsburgh, Pa. He graduated at Hamilton College in 1867 and at Auburn Seminary (Presbyterian) in 1870. He held pastorates in St Paul and Chicago until 1894, when he was called to the First Presbyterian Church of Pittsburgh. In 1898 he became professor of practical theology in Western Theological Seminary, Allegheny, Pa., and he identified himself prominently with his denomination's Board of Missions for Freedmen. Among his publications are many tracts, notably *More Light*, which had a wide circulation, works on hymnody, especially a frequently reprinted *History and Use of Hymns and Hymn Tunes*, *Abraham, the Typical Life of Faith* (1886), *History of the Preparation of the World for Christ* (1891), *Preparing to Preach* (1911).

BREED, ROBERT STANLEY (1877-) An American biologist, born at Brooklyn, Pa. He was educated at Amherst College, at the University of Colorado, and at Harvard. In 1902 he became professor of biology at Allegheny College and was there secretary of the faculty in 1907-10. He became known especially for his researches on the post-embryonic development of insects and for his contributions to scientific journals on the public milk supply. In 1903 he published *The Changes which Occur in the Muscles of a Beetle during Metamorphosis*.

BREED, brî'dê (Dutch, "the Broad"). A river of Cape Colony. It rises about 75 miles northeast of Cape Town, flows south, and empties into St Sebastian Bay (Map Cape Colony, E 9). It is navigable, by small vessels, for 40 miles.

BREEDING (AS *briëden*, to nourish, keep warm, from *brâd*, blood). A breed, in domestic animals, is a race, variety, or strain resembling the general type of the species, distinguished by particular characters or qualities which are transmitted and maintained. Breeds owe their origin to the tendency of animals toward variation and to natural and artificial selection. Under domestication the same kind of species of animals has changed naturally to a different extent and in a different direction as a result of environment. Certain variations have been found better adapted to specific purposes, and these variations have been perpetuated by man by restricting the coupling, i.e., by selection and breeding. This process, carried on consis-

tently through successive generations, has produced a group of animals of sufficiently marked characteristics, which are capable of being transmitted to the offspring, and which entitle these animals to be recognized as distinct breeds.

Plants, like animals, tend toward variation, and, as a result of this, the equivalent of different breeds, usually spoken of as varieties or strains, have been produced. The principles underlying the breeding of plants and of animals are essentially the same, but the methods of operation are not entirely analogous; hence the subjects of plant breeding and animal breeding can best be considered separately.

Plant Breeding. The variation in plants may be due to natural causes, as environment, etc., or it may be the result of design on the part of man, in which case it is secured by artificially crossing two or more races or varieties. Artificial variation is secured by fertilizing the ovules of one plant with pollen from another. Plant breeding is the fixing, by selection, of the desirable traits found in the variations, whether naturally or artificially produced. The farmer or gardener who seeks to improve his crop by planting seed from the most favored individuals is practicing plant breeding. This kind of plant breeding has been going on in all countries ever since the cultivation of plants was begun. The improvement of plants by selection from artificially produced variations is of more recent origin. The production of varieties by crossing has its basis in the sexuality of plants, a discovery of Camerarius in the last decade of the seventeenth century. Crossing is the fertilizing of a flower of one variety with the pollen of a flower of another variety of the same species. Hybridizing is the same operation, but between two species of the same genus. The scientific breeding of plants through the production of hybrids has as its basis Mendel's law (g.v.), first published in 1865 but passed unnoticed until about 1901. By this law, within certain limits the inheritance of parental characters and the subsequent behavior of the hybrid plants can be definitely foretold. Only a portion of the offspring will show true hybrid characters, and these are the ones to be selected for further breeding experiments. In the elucidation of these principles important work has been done by Bateson and Biffen in England, Johannsen in Denmark, Von Rümker and Frowirth in Germany, Von Tschermak in Austria, Nilsson-Ehle in Sweden, and Webber, Spillman, East, Emerson and others in the United States. De Vries, who is responsible for the "mutation theory," provides an additional method of securing material for plant breeding. He claims that new forms, which he calls mutations, may suddenly arise from species that have long been without evident variation and that by the recognition and utilization of these improved races of plants may be secured. The first artificial hybrid is said to have been produced by an English gardener, Thomas Fairchild, in 1719, when he crossed the carnation with the sweet William. The practical application of hybridization to plant breeding did not take place until the early part of the nineteenth century, when the investigations of Knight, an Englishman, and Van Mons, a Belgian, were made. In the United States the earliest investigators along this line were Joseph Cooper and James Thatcher. Since these pioneers, many persons have devoted their energies to the improve-

ment of races of cultivated plants. Conspicuous among these have been Hallet, of England; Rimpau, of Germany; Vilmorin, of France; and Hays, of the United States, all of whom have developed new and improved varieties of cereals; Lous de Vilmorin and his son, Henri de Vilmorin, of France; Rabbethge and Giesecke, of Germany, who have developed the sugar beet; Richter, Girard, and Burbank, who have worked with potatoes; Livingston with tomatoes; Clark and Hinson with Sea Island cotton; Webber with Upland cotton; Hovey and Dana with pears; Bull, who originated the Concord grape in 1849; Allen, Munson, Millardet, with grapes; Burbank with plums and berries. Many others have worked with all sorts of fruits and ornamentals.

In any system of plant breeding selection plays a most important part. Some natural variants or sports are propagated by cuttings or grafts, which is the most simple method of plant breeding. Others are grown from seed, and plants from these tend to variation. This tendency can be overcome only by continual rejection of all plants that depart from the desired type, seed being saved only from those which most nearly conform to the ideal type. By continuing this process through a number of years or crops, a race will be found that will closely resemble the type in all its individuals. The amount of care and labor involved may be seen from the statement that a breeder of sugar beets examined, in one season, more than 3,000,000 roots of an improved variety, only about 3000 of which were accepted for further trial.

When selection is practiced for producing new races or varieties of cultivated plants, there are a few axiomatic principles to be observed: Always continue selection upon the same lines, once it is begun. Great size and numerous parts cannot usually be secured in the same variety, nor are extraordinary earliness and great productivity found associated together. See HEREDITY; VARIATION; MUTATION; PLANT BREEDING.

Animal Breeding. The art of breeding animals until recently was founded on the practice of the most successful breeders, and its rules were almost exclusively empirical in their origin. They were not worked out on the basis of scientific investigation and experiment, but may be regarded rather as contributions to science than deductions from it.

Breeding has been practiced from the earliest times, the horse having apparently received more attention from the ancients than the other kinds of farm animals. The ancients evidently had some knowledge of the laws of heredity, although much stress appears to have been laid upon the exercise of external influences as well. The early breeders had no consistent system of selection—their standards of excellence were, in fact, constantly changing, so that the conception of the "best" differed widely from time to time, and this prevented any very high development of the most valuable qualities except in the development of the Arabian horse and the English race horse known as the Thoroughbred. Soon after the middle of the eighteenth century Robert Bakewell, of England, practiced a new system of breeding, based upon careful selection from a single variety or breed, and close breeding to develop certain desirable qualities. The crossing of different breeds had previously been held to be the road to improvement. He regarded the animals he worked with as plastic, and he sought so to mold these plastic forms

as "to give expression to his ideal conception of the qualities that constitute perfection." His work, and the following out of his theories by a long line of able breeders have given us many improved breeds of live stock, each adapted to special conditions and purposes.

Since Bakewell's time breeders have recorded many interesting experiences and observations, but so few underlying principles could be deduced from them that the breeding of animals was not placed on a scientific basis until the beginning of the present century. When good judges of live stock attempted to transfer the desirable characteristics of their animals to the next generation it was a game of chance, and though in many cases the breeder obtained satisfactory results there was much unavoidable loss of time and money. Modern scientific investigation has changed the situation. Microscopic studies of the germ cell and of embryonic tissues have revealed conditions which influence the developing organism, and the discovery of the Mendelian principles has yielded such positive results that now it is possible in many cases to predict, with a reasonable degree of certainty, what characters may be inherited. Experimental evidence has shown that many characteristics of an individual may be inherited independently, that some of these unit characters are dominant over others, that all ancestors of the same degree do not contribute equally to the hereditary qualities of the offspring, and that Weismann's theory of heredity and Galton's ancestral law, in their original forms, were founded on incorrect assumptions.

These discoveries are of commercial importance, as they show how feed and other environmental conditions are limited by heredity. The breeder to-day need not work in the hap-hazard manner which was necessary in the closing years of the nineteenth century.

Mendel and his followers have shown that many characteristics run in pairs—one a masked or dominant character, the other a masked or recessive character. By proper mating the recessive character can be separated from the dominant one and new combinations can be made. By successive matings recessive characters can be bred pure, though it is difficult to eliminate the recessive character from the dominant so that the dominant character may be bred true. Thus, when black cattle are crossed with red cattle the offspring are usually black, not roan or some mixture of red and black. The Mendelian explanation is that these black calves are in reality crosses containing red, though the red is suppressed.

Experiments also indicate that white cattle are dominant to black, so that from these crosses it is easier to develop a strain of pure black cattle than it is to establish a white strain. In horses the relative dominance of color is probably in the following order: white, roan, gray, bay or brown, black, and chestnut or yellow.

An important application of these principles is the inheritance of sex, which is now thought to be similar to the inheritance of other characters. If further experiments substantiate this possibility, the breeder will be able to control to some extent the sex of his animals. Another application is the so-called sex-limited inheritance, which can be defined as inheritance where the same characteristic behaves differently in the two sexes. A familiar instance of this is the barring of feathers in Plymouth Rock fowls.

The male but not the female will transmit the barred condition to all its progeny when mated to brown Leghorns. The females will transmit it only to the male progeny. According to experiments reported by Dr. Raymond Pearl, of the Maine Experiment Station, high egg-laying capacity is transmitted through the male. If this should prove to be true of all breeds of fowls, more attention must be given to the male than to the female breeding stock if high egg production is the object of the breeder. High milk production is also believed to be inherited through the male line, but positive proof is yet lacking.

The selection of the male is further important because he impresses his characters upon a larger number of offspring than does the female.

In developing new strains and new breeds, the breeder does not make new characters, he merely perpetuates the desirable and eliminates the undesirable characters which are presented to him by making new combinations. New characters may arise "spontaneously" or by "mutation" from unknown causes. These the breeder can take advantage of if it is desirable to have them perpetuated, because the characters which originate in this way usually prove to be dominant. The variation of animals is greater under domestication than in nature, consequently the breeder frequently finds many new variations to choose from in the development of new strains or types.

There are two difficulties, however, which are encountered when the Mendelian principles are applied to practical breeding operations. In the first place, not all characters are unit characters inherited in pairs, and, secondly, when they are inherited in pairs the dominance of one of the paired characters is not always perfect. At present there is no satisfactory explanation of the imperfections of dominance.

Mendelian principles are theoretically alike valuable to the plant and animal breeder, but in their application they have been of more service to the plant breeder than to breeders of animals. But they have shown why inbreeding brings uniformity of type and why and when pedigree counts and when it does not. They also throw considerable light on the generalization that "like tends to beget like" and under what conditions some characters may remain latent.

Selection and the coupling of animals is the practical application of the principles of breeding as briefly enumerated, and its successful accomplishment requires the ability to conceive or comprehend an ideal and to maintain or develop it. In the coupling of animals several systems or practices are recognized, depending upon the relationship of the sire and the dam, as in and-in breeding, line breeding, crossbreeding, etc. In-and-in breeding, or close breeding, is the coupling of animals nearly related. Regarding the closeness of relationship implied in these terms, it not only appears that no definite rule has been established, but also that different writers use them with a somewhat different shade of meaning. The object sought is to establish desired forms or qualities with the greatest certainty and in the least time. The fewer the ancestors the easier it is to breed animals with the desirable characteristics. Those who object to close breeding hold that it carries with it danger of loss of constitutional vigor and fertility in the offspring, loss of size, and sometimes malformation. This danger un-

doubtedly depends upon the extent to which the practice is carried and upon the character of the animal. The more purely bred and uniform in type the stock, the greater does the probable danger become; while with miscellaneous bred stock the evil effects are comparatively slow in showing themselves. All the great breeders have practiced close breeding to a greater or less extent, apparently for the purpose of retaining and fixing certain desirable characteristics that have been developed by modified conditions. They evidently intended to breed together animals of the same qualities, regardless of relationship. The practice is generally conceded to be an important means of improvement, when judiciously followed.

Closely allied to in-and-in breeding is line breeding, which, as applied to a distinct system, is comparatively new. It consists in breeding within a few closely related stocks or families, no animals being interbred which are not closely connected in the general lines of their blood. Owners of pure-bred stock are usually line breeders. The danger of a loss in size, vigor, and fertility is less than with inbreeding. Cross-breeding is the coupling of animals of distinct breeds or a cross between a distinct breed and an animal of unknown breeding or "native."

The supposed influence of a previous sire, or "telegony," believed in by many breeders, has been treated experimentally many times, but thus far the evidence is negative. The classic instance of Lord Morton's mare, usually cited by believers in telegony, has now been discredited by the Penycuik Experiments of Professor Ewart. Maternal impression, another persistent belief of many breeders, also lacks scientific proof. Practical breeders believe that "acquired characters" are inherited, but this is stoutly denied by Weismann and his followers.

No great progress can be made in breeding animals so long as the breeding stock consists of unsound individuals or is of unknown breeding. Several States, beginning with Wisconsin in 1906, have passed legislation relative to the registering and control of stallions in order to prevent fraud and to eliminate unsound sires. Another movement to improve stock by grading up with pure-bred sires is by cooperative or circuit breeding. This is done where a community of farmers interested in the improvement of any one breed form an association binding themselves to advance the interests of that breed and to use only pure-bred males. This plan has been the most successful in improving dairy cattle in connection with cow-testing associations, which purchase the best bulls obtainable.

Of late an increasing amount of attention has been given to systematic investigations upon the principles of breeding, the laws of heredity, transmission of qualities, etc. The United States Department of Agriculture has undertaken studies in animal breeding in cooperation with a number of the agricultural experiment stations, using horses, sheep, cattle, and poultry. In 1903 the American Breeders' Association was formed for the object of advancing knowledge of this subject. For a more detailed discussion of the theories, principles, and practice of breeding animals, the reader is referred to the articles on BIOLOGY; HEREDITY; MENDEL'S LAW; WEISMANNISM. Consult: Darwin, *Variations of Plants and Animals under Domestication* (London, 1885); Castle, *Heredity in Relation to Evolution and Animal Breeding* (New York, 1911);

Davenport, *Principles of Breeding* (Boston, 1907); Ewart, *The Penycuik Experiments* (London, 1899); Ewart, "The Principles of Breeding and the Origin of Domesticated Breeds of Animals," *Annual Report of Bureau of Animal Industry, U. S. Dept. of Agr., 1910*; Kronacher, *Gesundzucht der Zuchtungsbiologie* (Berlin, 1912); Marshall, *Breeding Farm Animals* (Chicago, 1911); Pearl, *Inheritance in Poultry* (several bulletins from the Maine Experiment Station); Wilson, *Principles of Stock-Breeding* (London, 1912). The different breeds of live stock are considered under CATTLE; HORSE; SWINE; POULTRY, ETC.

BREED'S HILL. The hill in Charlestown (Boston), Mass., on which the battle of Bunker Hill was fought, and which is the site of Bunker Hill Monument. It is somewhat south of the true Bunker Hill.

BREESE, KIDDER RANDOLPH (1831-81). An American naval officer, born in Philadelphia. In 1846 he entered the navy as a midshipman. At the beginning of the Civil War he served as commander of the third division of Porter's mortar flotilla, in the attacks on New Orleans and Vicksburg (1862), and, as lieutenant commander, participated in the important operations on the Mississippi and its tributaries, during 1863 and 1864. He was then appointed fleet captain of the North Atlantic blockading squadron, in which capacity he commanded the storming party in the naval assault on Fort Fisher (g.v.), Jan. 15, 1865. In 1874 he was raised to the rank of captain.

BREEZE. See BEAUFORT SCALE.

BREFELD, brä'fēlt, OSKAR (1839-). A German botanist, born at Telgte, Westphalia. He was appointed professor of botany at Eberswalde (1878), Münster (1884), and Breslau (1898). He retired in 1907. His scientific investigations may be said to cover the field of mycology. It was he who introduced the so-called "gelatin cultures" which at one time gained such wide application in bacteriology. He published a series of volumes entitled *Untersuchungen aus dem Gesamtgebiete der Mykologie* (1872).

BREGENZ, brä'gēnts (anciently, Lat. *Brigantium*, the town on the heights, from Celt. *brigh*, *brig*, heap, elevation). The capital of the Austrian crownland of Vorarlberg, situated about 1295 feet above sea level, on the eastern shore of Lake Constance (Bodensee), 6 miles southeast of Lindau by rail, and 80 miles west-northwest of Innsbruck. It consists of the old, or upper town, and the new town, almost surrounding the former. Bregenz has a town hall and a museum containing a collection of Roman antiquities found in the neighborhood. Its position on the lake has made it an important port and commercial centre. Its chief trade is in grain, cattle, and products of the cotton and silk factories of Vorarlberg. Pop. of the district in 1910, 34,743. Under the name of Brigantium the town was a Roman station, and in the Middle Ages the seat of the powerful counts of Bregenz. In the sixteenth century it passed to the house of Hapsburg. Consult *Helbrook, Die Bevölkerung der Stadt Bregenz* (Innsbruck, 1912).

BRÉGUET, brä'gä', ABRAHAM LOUIS (1747-1823). A French mechanician and watchmaker, a native of Neuchâtel. The astronomical and nautical instruments invented by him were noted for the perfection of their workmanship. His improvements in watches included the use of rubies

in pivot holes. He fled to London during the Reign of Terror, but returned after the ninth Thermidor. A grandson, LOUIS FRANÇOIS CLEMENT (1804-83), also a watchmaker, had charge of establishing the first telegraphic line in France. He also invented the system of electric clocks, for transmitting time to a distance and published a number of works on the telegraph. He wrote *Télégraphie électrique*.

BREHM, brām, ALFRED EDUARD (1829-84). A German naturalist and traveler. He was born in Reuthendorf, Feb. 2, 1829, and died there Nov. 11, 1884. He studied natural history and ornithology with his father, who was a celebrated ornithologist. From 1847 to 1854 he traveled through Egypt, Nubia, and the Sudan, and later in Spain, Lapland, Abyssinia, and Siberia. In 1862 he was appointed director of the Zoological Gardens in Hamburg, and from 1867 to 1874 he was director of the Berlin Aquarium. He published in 1863 the first edition of the *Illustriertes Thierleben*, the most important work of its kind at that time.

BREHM, CHRISTIAN LUDWIG (1787-1864). A German ornithologist. He was born in Schonau, near Gotha, studied theology in Jena from 1807 to 1809, and held several pastorates. He made a collection of 9000 European birds, afterward bought by Rothschild in 1897 for his museum at Tbing. His most valuable works are *Beiträge zur Vogelkunde* (3 vols., 1821-22), *Lehrbuch der Naturgeschichte aller europäischen Vogel* (2 vols., 1823-24), *Ornis* (3 parts, 1824-27), *Handbuch für Liebhaber der Stuben-, Haus- und aller der Zuhaltung wertigen Vogel* (1832), *Der vollständige Vogelfang* (1855), *Die Eier der europäischen Vogel nach der Natur gemalt* (in collaboration with Baedeker and Passler, 1855-67).

BRE'HON (Ir. *breathamh*, *breithamh*, from OIr. *bithon*, judge, from *bith*, *bith*, decision, judgment). **LAW**. The ancient laws of Ireland. In the form in which they have come down to us they consist of a collection of law tracts which were compiled by different hands and at different times and committed to writing probably in the tenth century of our era. M. d'Arbois de Jubainville has shown that the *Senchus Mór* is really made up of treatises belonging to different periods, of which that upon Immediate Seizure is the oldest. While some of the other treatises must be of much later date, this tract cannot in its present form be later than the close of the sixth century, because it contains no trace of the right of succession accorded to women by an Irish council of c. 600, while at the same time it cannot be anterior to the introduction of Christianity, because it contains mention of altar furniture amongst things seizable. These laws derive their name from the *Brehon*, a class of hereditary lawyers and judges, by whom they were preserved by oral tradition and ultimately embodied in written form. These tracts—the most important of which are the *Senchus Mór*, or 'Great Book of the Ancient Law,' and the *Book of Acall*—consist of brief and sometimes rude statements of the law, often expressed in verse, accompanied by elaborate annotations and commentaries made by successive *Brehon* through whose hands they passed. In this way the primitive body of law was modified from generation to generation to conform to the growth of the Irish people in Christianity and civilization. In its original form this law does not differ widely from that of other early systems, such as the

Twelve Tables of Rome, the Mosaic Law, and the barbaric codes of the Middle Ages, most of its provisions having to do with crimes of violence, and the commutation of the penalty for such crimes by money or other payments. The poet Spenser, in his *View of the State of Ireland*, written in 1596, describes the Brehon Law as "a rule of right unwritten, but delivered by tradition from one to another, in which oftentimes there appeareth great share of equity, in determining the right between party and party, but in many things repugning quite both to God's law and man's." This criticism might have been modified if Spenser had been aware of the fact that pecuniary compensation for manslaughter was a salutary device of primitive society for mitigating the horrors and inconveniences of private vengeance, and that it had prevailed in England as well as in all other European countries (See BLOOD FEUD, BLOOD MONEY). As has been seen, he was mistaken, also, in believing that the Brehon Laws were, at the period of his visit, an unwritten code, though they may still, in that backward state of society, have depended largely on tradition for their preservation. Many manuscript collections of these laws, dating from the fourteenth to the sixteenth century, still exist in public and private libraries in England, Ireland, and Belgium. The first translation into English was made by O'Donovan and O'Curry in four large volumes and published in 1865-69. Notwithstanding their deficiencies, the Brehon Laws are the most remarkable code possessed by any ancient people, and reveal a high degree of civilization (See BRETTIS AND SCOTT). Sir Henry Sumner Maine has considered the primitive Irish law at length and with great learning in his *Lectures on the Early History of Institutions* (London, 1876). Consult also Ginnell, *The Brehon Law* (London, 1894); D'Arbois de Jubainville, *Études sur le droit celtique* in vol. vii of the *Cours de Littérature celtique* (Paris, 1895); Joyce, *Social History of Ancient Ireland*, vol. 1, pp. 168 et seq. (London, 1903); Hyde, *Literary History of Ireland*, pp. 583 et seq. (London, 1906).

BREISACH, brî-zâc' (anciently, Lat. *Mons Brisacius*, possibly from Celt. *brig*, elevation, hill + Teut. *aha*, water), ALZ. A very old town of the Grand Duchy of Baden, situated on a basaltic rock 260 feet above the Rhine, on its right bank, about 12 miles west of Freiburg (Map Germany, B 4). It is a thriving little town, with manufactures of wall paper, beer-brewing, and wine, and a trade in lumber and cattle. As early as the time of Julius Caesar Mons Brisacius was known as a strong military position and was taken by Ariovistus when he invaded Gaul. During the Middle Ages it frequently changed masters and, after having been for a time a free Imperial city, became a possession of the house of Austria. Its military importance made it a battle ground for the French and Austrians in the seventeenth and eighteenth centuries. The French destroyed its fortifications in 1744 and, during the War of the Revolution in 1793, burned the town. In 1805 the French handed it over to the house of Baden. Pop., 1890, about 8000, 1900, 3500, 1910, 4707. Consult Coste, *Notice historique sur la ville de Vieux-Breisach* (Mulhouse, 1860).

BREISGAU, brîs'gau (Ger. *Breis*, for *Breisach* + *Gau*, district). A former district in the southwest corner of Germany which extended

along the right bank of the Rhine from Basel to Kiel. In the fourteenth century it belonged to the Hapsburgs; in 1457, to Baden; there were frequent changes of masters, but eventually Austria became mistress of most of it. She was dispossessed in the Napoleonic wars, and since 1810 the whole of Breisgau has been a part of Baden.

BREITENFELD, brî'ten-fêlt (Ger. *breit*, broad + *Feld*, plain, field, referring to the plain near by). A village in Saxony, about 5 miles north of Leipzig, noted as the scene of two battles between the Swedes and the forces of the German Empire. On Sept. 17 (N.S.), 1631, Gustavus Adolphus and the Elector of Saxony overthrew Tilly at Breitenfeld, shattered his army, and saved the cause of Protestantism, which had been imperiled by the fall of Magdeburg. Eleven years later, Nov. 2, 1642, Torstenson, the pupil of Gustavus, signally defeated the Archduke Leopold and General Piccolomini on the same spot. Breitenfeld also had some of the fighting around Leipzig in October, 1813. Consult Opitz, *Die Schlacht bei Breitenfeld 1631* (Leipzig, 1892).

BREITHAUPT, brî'thaupt, JOHANN AUGUST FRIEDRICH (1791-1873). A German mineralogist. He was born at Probstzella, Thuringia, and studied at the University of Jena and at the Academy of Freiberg. Here he received an appointment in 1813 as teacher and lapidary and in 1827 became professor. He wrote *Ueber die Echtheit der Krystalle* (1816) and *Vollständige Charakteristik des Mineralsystems* (1829; 3d improved ed., 1832). He also continued Hoffmann's *Handbuch der Mineralogie* (3 vols., 1836-47), adding five chapters to this valuable work. Towards the close of his life he became almost totally blind. He increased the nomenclature of crystallography and carefully examined almost all the minerals known in his day and took 3000 measurements of calcite alone. The opening of the great coal fields at Zwickau, in Saxony, was due to his initiative. His other publications include *Die Paragenesis der Mineralien* (1849) and *Die Bergstadt Freiberg* (1825; 2d ed., 1847).

BREITKOPF, brî'tkôpf, JOHANN GOTTLIEB IMMANUEL (1710-94). A German printer and proprietor of a well-known publishing house of Leipzig, established in 1664 and known as Breitkopf & Härtel since 1795. He was born in Leipzig and graduated from the university of that city. His investigations in history and mathematics led him to a scientific study of printing, which resulted in a more artistic development of German text and an improvement of musical notation (1754). At the time of Breitkopf the old form of musical notation had been almost forgotten. Compositions were either written or engraved, and the form of printing music now principally used is undoubtedly due to his initiative. His writings include the following: *Ueber die Geschichte der Erfindung der Buchdruckerkunst* (1779); *Ueber den Druck der geographischen Karten* (3 parts, 1777-79); *Ueber Bibliographie und Bibliophilie* (1793).

BREITMANN, brî'tmân, HANS. See LAND, CHARLES GODFREY.

BREKELINKAM, brâ'ke-lêp'kâm, QUIRYN (1620-68). A Dutch genre painter. He was born at Zwammerdam, near Leyden, and was probably a pupil of Gerard Dou. He depicted with great fidelity to nature scenes from folk

life, market scenes, and domestic interiors. His works are characterized by simplicity and remarkably effective coloring. The best known are: "The Fireside" (1664, Rijksmuseum, Amsterdam); "Monk Writing" (Louvre); "Consultation" (ib.); "Interior" (1662, Museum of Lille); "The Sandwich" (Leyden Museum); "Saying Grace" (Cassel Gallery); "Game of Cards" (Brunswick Museum); "A Brazier" (Augsburg Gallery).

BREMA, MARIE. An English opera singer, born in Liverpool. After studying under Georg Henschel, Madame Bessie Cox, and Alfred Blume, she made her début at Oxford in the rôle of Adrienne Lecouvreur. In 1891 she appeared at the Shaftesbury Theatre in the part of Lola in *Cavalleria Rusticana*. In the following year she sang at Covent Garden in the Royal Italian Opera, taking the rôle of Guinevere in Bemberg's *Elaine*. Later she sang in *The Ring* at the Metropolitan Opera House in New York, at the Bayreuth Festival, the rôles of Delilah and Orphée at Brussels, and that of Brunnhilde in Paris. In 1911 she produced *Orpheus* in the Savoy Theatre, London, and in 1912 she appeared in *The Ring* in the Wagner Festival in Brussels.

BREMEN, Ger. pron. brâ'men (*Brema, Bremen* of the eighth century, possibly the *Pharaurum* of Ptolemy). A city of northwestern Germany, capital of the state of Bremen, in lat. 53° 5' N. and long. 8° 48' E., on both banks of the Weser, 46 miles from the North Sea and 71 miles by rail southwest of Hamburg. The city covers about 10 square miles; at the census of Dec. 1, 1910, its population was 247,437, as compared with 163,297 in 1900, 125,000 in 1890, 113,000 in 1880, and 81,000 in 1870. Bremen is divided into the old and the new town—the former on the right, the latter on the left bank of the river, which is spanned by four bridges. The old town has crooked, narrow streets and a quaint appearance; it forms the business district of the city. The new town has broad, straight, well laid-out streets lined with tall, handsome buildings. The ramparts and bastions round the old town have long been leveled, and the site converted into public promenades and gardens, which are laid out in excellent taste. The more important buildings include: the Gothic town hall (Rathaus), which stands on the market square of the old town and was begun about 1405—its celebrated wine cellar has been immortalized by Wilhelm Hauff; the cathedral of St. Peter (now the Lutheran parish church), built in the twelfth century on the site of Charlemagne's wooden church; the thirteenth-century church of St. Ansgarius, with a spire over 300 feet high; the Gothic exchange (1867); the post office (1878); the law courts (1891-95).

The situation of Bremen makes it a great emporium of northwestern Germany, and the city is known especially for its sea-borne foreign trade. It has excellent rail connections with the great industrial centres of Germany, and engineering work carried on in 1887-99 enables large ocean-going vessels to come directly to the city. Altogether there are four harbors, including the "Safety" or original harbor. Bremen carries on an extensive commerce with European countries, the United States of America, the West Indies, Africa, the East Indies, China, and Australia, and is the largest port in Germany after Hamburg. This commerce has shown a remarkable development since 1847, rising from less than \$46,900,000 in that year, to

nearly \$303,700,000 in 1891, to over \$622,000,000 in 1905, and to about \$995,889,500 in 1911 (The commerce figures in this article relate to the state of Bremen, but they are practically coincident with those of the city.) The chief imports are tobacco, coffee, sugar, cotton, rice, skins, dyewoods, wines, timber, hemp, etc. Articles of food and raw materials constitute nearly 80 per cent of all the imports, whereas manufactured articles make up less than 20 per cent. This partly explains why the United States has a preponderance over other countries in respect of those imports. In 1850 imports from the United States were less than twice those from the United Kingdom, in 1911 they were about ten times as great. In 1911 imports and exports, stated in marks, amounted to 2,124,730,000 and 2,047,814,000 respectively (including trade with the German Empire). The following table shows the trade by most important countries in 1910 and 1911, in thousands of marks

	Imports		Exports	
	1910	1911	1910	1911
German Empire	692,773	731,688	931,692	1,047,753
United States	618,986	751,477	215,787	215,786
Australia	107,825	100,951	35,396	37,949
Russia in Europe	89,064	124,524	126,095	122,331
United Kingdom	65,287	70,206	100,622	150,471
Argentina	52,361	41,838	30,742	39,012
British India	43,668	41,065	9,291	12,017
Brazil	32,100	32,720	12,484	13,071
Austria	30,782	23,085	125,068	141,200
Total, incl other	1,908,428	2,124,730	1,879,437	2,047,814

The exports of Bremen consist of woolen goods, linens, glass, rags, wool, hemp, hides, oil cake, wooden toys, etc. Large quantities of tobacco are reexported. With the exception of Hamburg, no Continental port ships so many emigrants to the United States as Bremen. Bremen has manufactures of woollens and cottons, cigars, paper, and starch, and extensive shipbuilding yards, breweries, distilleries, and sugar refineries. It has steam communication with New York, Hull, Havana, the north coast of South America, etc., by vessels of the North German Lloyd Steamship Company.

In the over-sea trade there entered in 1911 6083 vessels of 4,516,782 tons net, and cleared 6228 of 4,479,335 tons net. The growth of Bremen's own merchant marine may be seen from the following figures:

Year	Vessels	Tonnage	Year	Vessels	Tonnage
1862	240	79,000	1892	405	406,000
1862	277	134,000	1900	571	583,000
1872	252	174,000	1905	632	693,870
1882	344	299,000	1911	713	893,767

The city is governed by the same powers as the state (see the following article). Bremen owns its gas works, water works, and electric plant. The municipal management of these undertakings has proved to be a great benefit to the citizens, besides yielding an increasing annual net income to the city treasury.

The street cars are in the hands of private companies, paying the city one-fourth of all their net income in excess of 5 per cent on the capital stock, in addition to a tax of 1 per cent on the gross income and all ordinary taxes levied upon business establishments.

The street cleaning, the health department, and all that goes to make the city clean and

healthful, are well administered, as may be seen from the following figures of death rates in the city and country districts, per thousand. 1894, city, 16.76, country, 22.33, 1898, city, 16.69, country, 21.70, 1904, state, 13.8.

The public schools are maintained and controlled by the city. In addition to the elementary schools, there are a high school, a commercial school, and a number of trade schools. Among the charitable institutions of the city there are three orphan asylums, two homes for neglected children, several hospitals, etc. It is interesting to note that Bremen spends nearly twice as much money on education as on police.

History. Bremen, mentioned in 782 as a missionary centre, was made the seat of a bishopric by Charlemagne in 788. In 845 the see of Hamburg was united to that of Bremen, and the latter became the capital of the new archiepiscopal diocese. In 965 Bremen was made a market town and was placed under the jurisdiction of the archbishop, but by the thirteenth century it had succeeded in acquiring virtual independence in secular affairs. It extended its trade to England and Scandinavia, founded a number of colonies, and ruled over both banks of the Weser to the sea. It joined the Hanseatic League in 1276, but was expelled, readmitted, and expelled again, for selfishness. The inhabitants became fervent Protestants, joined the Smalkaldic League in 1532, and in 1547 decisively defeated an Imperial army at Drakenburg. In two wars (1654, 1666) Bremen won its autonomy from Sweden, to whom the secularized diocese had been ceded (to form a duchy) in 1648, but it was not till 1741 that the independence of the city, which had been made a free Imperial town in 1646, was acknowledged fully. In 1810 Bremen was incorporated into the French Empire, but it became free in 1813 and in 1815 was made a member of the German Confederation. As a member of the German Empire, it remained outside of the *Zollverein* till 1888. A popular revolution in 1904 made the government of the city partly democratic, the liberal régime was confined in 1933 and 1934. The present constitution was adopted in 1854. The Duchy of Bremen was ceded by Sweden to Hanover in 1719.

Consult *Denkmale der Geschichte und Kunst der freien Hansestadt Bremen* (3 vols, Bremen, 1870), Reese, *Jahrbuch für Bremische Statistik* (Breslau, 1892), *Die Freie Hansestadt Bremen und Umgegend* (Bremen, 1893), V. Buppen, *Geschichte der Stadt Bremen* (Bremen, 1898), J. Bollmann, *Bremisches Staats und Verordnungsrecht* (Bremen, 1904).

BREMEN. A northwestern state of the German Empire, with the title, since 1815, of Freie Hansestadt Bremen. It consists of 18 communes, the bulk of which form a territory on both sides of the Weser, surrounded by the Prussian province of Hanover and the Grand Duchy of Oldenburg and containing the city of Bremen, which is 46 miles from the sea. The remaining territory consists of two detached towns, Vegesack, at the northern boundary of the main territory and on the right bank of the Weser, and farther north the port of Bremerhaven, 35 miles from Bremen City. The total area of the state is 25,640 hectares, or 90 square miles, of which Bremen city comprises about 10 square miles and Bremerhaven a little more than one square mile. There is some agriculture, and in 1912, 1402 hectares were under rye, 1538 oats,

1191 potatoes, and 2591 meadow. The population in 1871 was 122,402; in 1880, 156,723 (showing an increase of 27.3 per cent); in 1890, 180,443 (14.1); in 1900, 224,882 (21.9); in 1910 (census of December 1), 299,526 (28.5). Of the last number 259,658 (86.7 per cent) were returned as Protestants, 22,233 (7.42) Roman Catholics, and 14,472 (6.2) Jews. Bremen city had 247,437 inhabitants in 1910. Bremerhaven 24,165, and Vegesack 4236. Bremen entered the North German Confederation in 1866 and the German Customs Union in 1888. The state has a republican form of government under a constitution dated March 8, 1840, and revised Feb. 21, 1854, and Jan. 1, 1894. The sovereignty is vested in the Senate and the Convent of Burgesses (Bürgerschaft), the former the executive and the latter the legislative power. The Senate consists of 16 life members, each of whom is elected by the Convent, on presentation by the Senate. The Senate elects two of its members burgomasters, who direct its affairs alternately through a ministry of 12 members, each of whom is a senator. The Convent of Burgesses consists of 150 members chosen for six years by an unequal suffrage. The commerce and shipping of the state of Bremen are treated in the article on Bremen city.

BREMER, brä'mër, FREDRIKA (1801-65). A Swedish novelist, born near Åbo, Finland, and removed in 1805 to Sweden. Her father was an ironfounder, wealthy and somewhat stern, her mother severe and impatient, the child affectionate, passionate, and restless, misunderstood and hindered in development. Her first writing was youthful poetry in French, produced when she was eight years old. Nursery dramas and a journal followed, with foreign travel that left her "conscious of being born with powerful wings, but conscious of their being clipped." She turned to works of charity and, to increase her means for these, published anonymously a series of romances under the general title, *Sketches of Every-Day Life* (1828-48). The first of these was *Axel and Anna* (1828). A second volume, *The H. Family* (1829-30), was a sensational success, and subsequent volumes won her an international public. She passed two years (1840-51) in America. Her early novels excel in descriptions of every-day middle-class life. They have the charm of unaffected simplicity and quiet humor. Noteworthy among them are: *Axel and Anna* (1828); *The President's Daughters* (1834); *Nina* (1835); *The Neighbors* (1837); *The Home* (1839). Later novels disclose the reformer, advocating philanthropy, religion, and especially the equal rights of women. Of these, *Hertha* (1857) and *Synkonif* are the best. Her verse is unimportant. Of her books of travel, *Homes in the New World* (1853) contains her impressions of America. She died at Årsta, Dec. 31, 1865. An English life of Miss Bremer, with unpublished writings, appeared in 1868. Her best works have been translated into nearly all European languages. Consult Richard Petersen, *Fredrika Bremer* (Copenhagen, 1892).

BREMERHAVEN, brä'mër-hä'ven (Ger. port or haven of Bremen). A port on the Weser, about 10 miles from its mouth, founded by Bremen in 1827, on ground acquired from Hanover, and now a part of the Bremen state (Map: Germany, C 2). (See BREMEN.) There is quayside for the larger ships that come to Bremen, the harbor being excellently equipped

for this purpose. Workshops and dry docks of the North German Lloyd Steamship Company are situated here. Outside of shipping, shipbuilding is the chief industry. Pop., 1870, 10,000; 1880, 14,000; 1890, 16,000; 1900, 20,300; 1910, 24,165.

BREMER-TON, brēm'er-tūn. A city in Kitsap Co., Wash., 28 miles west by south of Seattle, on Puget Sound, and on the line of the Washington Steamship Company (Map: Washington, C 3). It is the seat of the Puget Sound navy yard, occupying 240 acres and valued, with its adjuncts, at \$10,000,000. Bremerton had the largest (at the time of its completion in 1912) dry dock in the United States, being 827 feet long and controlling a depth to the sea at mean low tide of 42 feet. It contains, also, a municipal park and playground on the water front, a public library, an athletic park, four theatres, and a skating pavilion. There are saw mills, machine shops, cigar and paint factories, a creamery, sheet-metal works, and an ice plant. Pop., 1910, 2993.

BREND'AMOUÉ, brēm'dā'mōor', RICHARD (1831-). A German wood engraver. He was born in Aix-la-Chapelle and studied engraving in Cologne. He is known chiefly as the founder, in 1856, of the well-known xylographic establishment in Dusseldorf, which was followed by similar establishments in other German cities. The illustrations for Zimmermann's *Oberhof*, after the drawings of B. Vautier (1863), and those of the eight frescoes by Alfred Rethel in the City Hall at Aix-la-Chapelle are among his most remarkable productions.

BREN'DAN, or **BREN'AINN**, SAINT, of Clonfert (484-577). An Irish saint and hero. He was born at Littis li or Staggum li, now Tralee, county Kerry, southwest Ireland; he was educated under monastic influences and became a priest, but, filled with a great desire to travel, went on a year's journey which took in the western and northern islands, e.g., the Hebrides, Shetland, and Faeroe Islands, and also Brittany. Returning, he went with a large party to the continent of Europe and to unknown lands, the smaller "Fortunate Isles." Returning from his second voyage, he founded the monastery in what is now Clonfert, in county Longford, central Ireland. Later he visited Iona and the mainland of Scotland. His reputation as a traveler being thus established, he was made the subject of a legend in which angels became his guides and strange experiences befell him. He died in 577, and his day in the calendar is May 16. Upon pre-Columbus maps "Saint Brendan's country," i.e., the scene of his supposed geographical discoveries, was just south of the island of Antillia and west of the Cape Verde Islands. Consult: B. C. Schröder, *Sanct Brandon* (Erlangen, 1871); John Lanigan, *Ecclesiastical History of Ireland*, vol. ii (Dublin, 1822); Francisque Michel, *Les voyages merveilleux de Saint Brandon à la recherche du paradis terrestre, légendes en vers du XII. siècle* (Paris, 1878); O'Donoghue, *Brendaniana* (Dublin, 1893); Gregory, *A Book of Saints and Wonders of Ireland* (London, 1907).

BREN'DEL, HEINRICH ALBERT (1827-95). A German animal painter. He was born in Berlin and studied at the Academy in that city with Krause and Burde, and in Paris under Couture and Palizzi. From 1854 to 1870 he lived chiefly at Barbizon, where he was on friendly terms with the famous painters who

lived there (see BARRIZON, PAINTERS OF), but his art remained distinctively German. In his delineation of cows and horses, and especially of sheep which are his favorite subjects, he showed deep understanding of the individuality of animals combined with high technical ability. Examples of his art are to be found in the National Gallery in Berlin and in the galleries of Hamburg, Weimar, Paris, and other European cities.

BRENDEL, KARL FRANZ (1811-68) A German musical critic, born at Stolberg-am-Harz, in Prussia. He was educated at the universities of Leipzig and Berlin, lectured on the history of music in Freiberg and Dresden, and in 1844 became editor in Leipzig of the *Neue Zeitschrift für Musik*, established by Schumann in 1834. At the same time he was appointed an instructor in musical history and aesthetics at the Conservatorium. He made the *Zeitschrift* the organ originally of the movement led by Wagner and Liszt, and, from 1861, of the Allgemeiner Deutsche Musikverein, founded in that year by himself, Liszt, and others for the purpose of reconciling hostile factions. He was president of the Verein until his death, and from 1856 to 1861 published a second periodical, *Anregungen für Kunst, Leben und Wissenschaft*. His publications include *Grundzüge der Geschichte der Musik* (1848), *Geschichte der Musik in Deutschland, Italien und Frankreich* (1852), *Die Musik der Gegenwart und die Gesamtansicht der Zukunft* (1864).

BRENEMAN, ABRAM ADAM (1847-) An American chemist and inventor, born in Lancaster, Pa. He graduated in 1866 at the Pennsylvania State College, and from 1869 to 1872 was professor of chemistry there. From 1875 to 1879 he was assistant professor of industrial chemistry at Cornell University, and from 1879 to 1882 professor. In 1882 he became a chemical expert, and a lecturer and writer on chemical subjects. He edited the *Journal of the American Chemical Society* from 1884 to 1893. Known as the inventor of a process, called by his name, for making iron non corrosive, he was an expert member of the municipal explosives commission of New York in 1906-09. His publications include *A Manual of Introductory Laboratory Practice* (1875, with G. C. Caldwell) and *A Report on the Fraction of Atmospheric Nitrogen* (1890).

BRENET, bre-nè', MICHEL (1858-) A French writer on the history of music. Her real name is Marie Bobillier. She was born, April 12, 1858, at Lunéville, lived some time at Strassburg and Metz, and after 1871 in Paris. Her works are the result of original and scholarly research. She has been a valuable and frequent contributor to the *Revue musicale*, *Tribune de St. Germain*, *Guide musical*, *Revue musicale italienne*, *Grande Encyclopédie*. Besides the special articles in these publications she wrote *Histoire de la Symphonie à orchestre jusqu'à Beethoven* (1882), *Orétry, sa vie et ses œuvres* (1884), *Jean d'Okéghem* (1893), *Claude Debussy* (1898), *Notes sur l'histoire du luth en France* (1899), *La jeunesse de Rameau* (1903), *Paléstrina* (1906), *La plus ancienne méthode française de musique* (1907).

BRENHAM, brén'am. A city and the county seat of Washington Co., Tex., 72 miles northwest of Houston, on the Gulf, Colorado, and Santa Fe, and the Houston and Texas Central railroads (Map Texas, D 4). Brenham

is the seat of the Blinn Memorial college, Sacred Heart Convent, and the Normal and Industrial College for Negroes, and has a public library, two parks of note, and fair grounds. It is in an agricultural, grazing, and cotton-raising region, and has cotton compresses, a cotton factory, a cottonseed oil mill, foundries, machine shops, a creamery, an ice factory, and manufactures of plows, wagons, soap, etc. Settled in 1844, Brenham was incorporated in 1866 and at present is governed under a charter of 1894, which provides for a mayor, elected every two years, and a city council. The water works are owned and operated by the municipality. Pop., 1890, 5209, 1900, 5968, 1910, 4718.

BRENKENHOF, brén'ken-höf, FRIEDRICH BALTHASAR SCHÖNBERG VON (1723-80) A Prussian statesman. He was born at Reichenburg, near Halle, and became equerry of Prince Leopold of Anhalt-Dessau. During the Seven Years' War he greatly facilitated the rapid marches of Frederick the Great by secretly and expeditiously furnishing the necessary supplies, chiefly horses, to the Prussian army. In recognition of his valuable aid, he was afterward invited to enter the service of Prussia and was entrusted with the task of restoring order and prosperity to the devastated eastern provinces. He rebuilt cities, founded settlements, encouraged the industries, and constructed numerous canals. After his death it was found that his accounts were irregular, and, in consequence, his estates were confiscated by the King, though afterward returned to the family. Consult Meissner, *Leben Brenkenhofs* (Leipzig, 1782).

BRENNAN, LOUIS See MONORAIL.
BRENNER, RICHARD (1833-74) A German explorer, born at Merseburg. During 1864 and 1865 he accompanied Baron von der Decken upon his expedition along the eastern coast of Africa. After the attack made upon the exploring party by the natives, Oct. 1, 1865, he made his way with great difficulty to Zanzibar and thence to Germany. On behalf of Von der Decken's family, and in association with Kinzelbach, he here organized an expedition for the purpose of ascertaining the fate of the Baron (1866-68). He afterward visited the southern part of the Galla country, of which region he was the first to prepare a chart. In 1870 he undertook an extensive commercial tour to Aden, the Persian Gulf, and the coast of East Africa.

BRENNER, VICTOR DAVID (1871-) An American sculptor and medalist. He was born of American parentage in Slavy, Russia, and came to the United States in 1890. He worked as a die cutter for several years, and in 1898 went to Paris, where he studied under Louis Oscar Roty. He received awards for his exhibits at the Paris Exposition and Salon of 1900, at the Pan-American Exposition in Buffalo in 1901, and at the Louisiana Purchase Exposition in St. Louis in 1904. Besides many medals he designed the seal of the New York Public Library and of the Fine Arts Federation of New York, and the Lincoln cent, and executed portrait medals of W. M. Everts, Collis P. Huntington, Whistler, Carl Schurz, Theodore Roosevelt, and others. He wrote *The Art of the Medal* (1910). Among his sculptures are the bust of Charles Eliot Norton (Fogg Museum, Harvard University). He is also represented by medals in the Luxembourg, the Munich Glyptothek, and the Metropolitan Museum, New

York. Consult Torrér, *Dictionary of Medalists* 1900).

BRENNER PASS. A mountain pass of the Tirol, Austria, the lowest over the main ranges of the Alps (q.v.). It is on the route joining Innsbruck with Bozen (Map: Austria, i, 3). The summit, which is 4470 feet above the sea, and 25 miles south of Innsbruck, lies on the watershed between the Black and Adriatic seas. It links the middle courses of the Inn and Adige, and bridges the broad double line of the central Alps. The Brenner Pass was in use by the Romans and other peoples 2000 years. It was made available for carriages in 1772, and in 1807 a railway was opened which passes over 67 bridges and through 22 tunnels (one of which is over 2800 feet long). It connects the railway systems of Germany and Austria with that of Italy and is the shortest route between central Germany and Italy. The railway was begun by the Austrian government when Venetia belonged to the Austrian Empire, with the view of facilitating the military operations and of restoring the commercial prosperity of Venice by making it the port of south Germany. The prosecution of the work was not arrested by the political changes which took place. A liberal commercial treaty between Austria and Italy, binding the two countries together in community of interest, restored the natural state of things, with which political animosities had long interfered. The pass takes its name from the village of Brenner at its summit. The most picturesque portions lie between Innsbruck and Gossensass. The steepest gradient is 1 in 40. The distance from Innsbruck to Bozen in a direct line is only 52 miles, but by the windings of the road or of the railway it is much increased. Consult Wanka von Rodlow, *Die Brennerstrasse* (Prague, 1900); Riehl, *Die Kunst an der Brennerstrasse* (Leipzig, 1908).

BRENNGLAS, brén'glas, ADOLF. A pseudonym of Adolph Glassbrenner (q.v.).

BRENTIA COMITIS. See BRAINE-LE-COMTE.

BRENN'NUS (Celt. *bréninn*, king, or Welsh and Ir. *bran*, raven). The Latin form of a Celtic name borne by several Gallic chieftains. 1. The most famous Brennus was that leader of the Gauls who about 390 B.C. crossed the Apennines and, hurrying through the country of the Sabines at the head of 70,000 men, encountered and overthrew the Roman army on the banks of the Allia. Had the barbarians immediately followed up their advantage, Rome might have been obliterated from the earth; but instead of doing so, they abandoned themselves to drunken revelry on the battle field, and gave the Romans time to fortify the Capitol, whither were removed all the treasures and holy things of the city, and to send the women and children to Veii (q.v.). When Brennus entered the gates he found that all the inhabitants of the city had fled, with the exception of the women and children and aged Senators, the last of whom, with pathetic heroism, had resolved not to survive the destruction of their homes; and so the chief among them, clothed in their robes of sacerdotal or consular dignity and sitting in the curule chairs, awaited the approach of their enemies and suffered death in majestic silence. Brennus, having plundered the city, now besieged the Capitol for six months. During the beleaguement occurred the famous night attack, which would have been successful had

not the cackling of the geese kept in Juno's temple awakened the garrison. At length, however, the Romans were compelled to enter into negotiations with the besiegers. They offered 1000 pounds of gold for their ransom, which was agreed to. According to Polybius (i, 6; ii, 18), Brennus and his Gauls returned home in safety with their booty; but the rather mythical Roman traditions affirm that, just as the Gauls were leaving the city, Camillus (q.v.), who had been recalled from banishment and appointed dictator, appeared at the head of an army, attacked them, and, in two bloody battles, slew them to a man. (Consult Livy, v, 33-49; Plutarch, *Camillus*, xvii, xxii, xxvii.) The whole story of Brennus is evidently a mere legend, based upon facts which the Roman historians, from patriotic motives, falsified. It is probable that the Gauls in reality held possession of parts of Italy for some time, and that their great rout by Camillus is pure fiction.

2. Another BRENNUS, who occupies a conspicuous place in history, was the Gallic chief who invaded Greece, 279 B.C., at the head of 150,000 foot and 61,000 horse. After desolating Macedonia, he forced his way through Thessaly to Thermopylae (278 B.C.). The Grecian army resisted for a time, but fled when he assailed them from the rear, by the same path which had caused the death of Leonidas (q.v.). Brennus rushed on with a division of his great host to Delphi, which he had resolved to plunder; but the Delphians, having taken up a very advantageous position on some rocks, resisted his further progress. Assisted by an earthquake and a terrible storm, and, according to reverential tradition, by the supernatural help of Apollo, they utterly routed the Gauls, who fled in dismay. Brennus was taken prisoner and killed himself in despair.

BRENT, CHARLES HENRY (1862-). An American. Protestant Episcopal bishop. He was born in Newcastle, Ontario; graduated from Trinity College, Toronto, in 1884; and, ordained a priest three years later, was settled first in Buffalo, N. Y., then (1888-1901) in Boston. At the end of this period he was elected Bishop of the Philippine Islands; he declined the bishopric of Washington in 1908. He lectured at the General Theological Seminary in 1904 and at Harvard in 1907, and for several years was one of the editors of *The Churchman*. In the Philippines he identified himself prominently with the crusade against opium, serving in 1911 as chairman of the American delegation to the International Opium Conference at The Hague. Besides his Seminary and Harvard lectures, published as *Adventure for God* (1905) and *Leadership* (1908), he wrote: *The Consolations of the Cross* (1902); *Liberty and Other Sermons* (1906); *A Glorious Ministry* (1910); *The Sixth Sense* (1911).

BRENTA (anciently, Lat. *Brinta*, or *Brentesia*). A river of north Italy. It issues from Lake Caldcazzoz in the Austrian province of Tirol, flows through the Sugana valley, then south through Venetia, finally turning eastward, and empties into the Gulf of Venice (Map: Italy, F 2). It originally emptied at Fusina, but to prevent inundations the main stream was diverted at Dolo southward into the Gulf of Venice just below Chioggia, while the old channel has been transformed into a canal between Venice and Padua. Below Bassano, where the Venetian plains begin, the river flows between

dikes The total length of the Brenta is 106 miles, of which 56 are navigable

BRENTANO, brén-táno, CLEMENS (1778-1842) A German novelist and poet of the Romantic school He was born in Ehenbreitstein, studied in Jena, lived in Frankfurt, Heidelberg, Vienna, and Berlin, and for a time at a cloister in Dülmen, near Münster (1818) Thence he went to Regensburg, Munich, and Frankfurt. He died in Aschaffenburg, July 28, 1842 Brentano's most characteristic poem is his *Romanzen vom Rosenkranz* (1852), a collection of subtle, mystic, and religious allegories, in which history, biography, legend, admiration for the Catholic church, and many other elements are cast into melodious form, while the drama *Die Gründung Prags* (1815) is a fantastic and bizarre production of undeniable power His best work is in short stories, particularly in his fairy stories The simplicity of his *Geschichte vom braven Kasperl* (1817) and of *Gockel, Hinkel und Gockeleia* (1838) is in pleasant contrast to the mystic romanticism of some of his other work His most enduring contribution to literature is the compilation, with Arnim, of German folk songs in *Des Knaben Wunderhorn* (3 vols, 1806-08) He was an erratic member of a whimsically brilliant family His grandmother, Sophie La Roche, had been a close friend of Wieland, his mother, Maximiliane, figures in Goethe's life, as does his sister, Bettina von Arnim (qv)

BRENTANO, FRANZ (1838-). A German philosopher, born in Maunenberg He was for a time a professor of philosophy in Würzburg and from 1874 to 1880 in Vienna His works comprise *Psychologie des Aristoteles* (1867), *Psychologie vom empirischen Standpunkte* (1874), *Neue Ratsel* (1878), *Vom Ursprung sittlicher Erkenntnis* (1889, Eng. trans., 1902), *Untersuchungen zur Sinnespsychologie* (1907), *Aristoteles und seine Weltanschauung* (1911), *Aristoteles Lehre vom Ursprung des menschlichen Geistes* (1911), *Von der Klassifikation der Psychischen Phänomene* (1911)

BRENTANO, LORENZ (1813-91) A German-American politician and editor, born in Mannheim After study in Heidelberg and Freiburg, he began legal practice, entered public life, and in 1848 was elected to the National Assembly at Frankfurt In 1849 he was placed in control of the Provisional Government of Baden, but soon fell under suspicion among his fellow revolutionists, and in 1850 fled by way of Switzerland to America He established *Der Leuchtturm*, a German antislavery journal, in Pottsville, Pa., and from 1862 to 1867 was editor in chief of the *Illinois Staatszeitung* in Chicago He was appointed to the American consulate at Dresden in 1872 and in 1876 was elected to Congress As editor of the *Staatszeitung*, he greatly aided the Federal cause during the Civil War period

BRENTANO, LUDWIG (1844-) A German political economist He was born in Aschaffenburg, Bavaria, studied at the universities of Dublin, Heidelberg, Munich, Würzburg, and Göttingen, and with Ernst Engel, the statistician, made an investigation of the English trades unions He was professor of political economy successively in Breslau (1873), Strassburg (1882), Vienna (1888), Leipzig (1889), and Munich (1891) His publications include *Die Arbeitergilden der Gegenwart* (2 vols,

1871), *Das Arbeitsverhältnis gemäss dem heutigen Recht* (1877), *Der Arbeiterversicherungszwang, seine Voraussetzungen und seine Folgen* (1881), *Ueber das Verhältnis von Arbeitslohn und Arbeitszeit zur Arbeitsleistung* (2d ed., 1893), *Agarpolitik* (1897), *Erbschaftspolitik* (1899), *Die Schrecken der überwiegende Industriestaat* (1901), *Die Wirtschaftliche Leben des Christlichen Altersums* (1902), *Die Entwicklung des Wertlehre* (1908), *Die deutsche Getreidesolle* (1911)

BRENTFORD The county town of Middlesex, England, on the Brent, at its confluence with the Thames, 10½ miles west of Waterloo Station, London, and where the Thames is crossed by a bridge leading to Kew It has extensive manufactories, among them being gin distilleries, breweries, soap works, saw mills, etc., and there are many market gardens in the vicinity Pop., 1891, 13,738, in 1901, 15,171, 1911, 16,571 Here Edmund Ironsides defeated the Danes in 1016, and in 1642 the Royalists, under Prince Rupert, defeated the Parliamentarians, under Colonel Hollis There are frequent allusions to it in English literature Consult Watts, "Old Brentfordtown," in the *Art Journal* (London, 1901)

BRENTON, WILLIAM (?-1674) An American colonist, prominent in the early history of Rhode Island He emigrated from England to Massachusetts in 1634 but removed to Portsmouth, R I., five years later, and in 1639 assisted in the founding of Newport He was Deputy Governor of Portsmouth and Newport, R I., from 1640 to 1647 and again from 1662 to 1665, was president of Providence Plantations from 1660 to 1662, and was Governor of Rhode Island and Providence Plantations, under the new charter of 1663, from 1666 to 1669 Brenton's Point, and Brenton's Reef in Narragansett Bay were named for him

BRENZ, biénts, JOHANN (1490-1570) A German reformer Under the influence of Luther he reorganized his church at Hall, Swabia, but at the time of the Smalkaldic War, in 1546, he was obliged to flee to Württemberg He was appointed minister of the Collegiate Church of Stuttgart in 1553, and is said to have been the first exponent of the Reformation there In the controversies between Zwingli and Luther he took the side of the latter, and with others wrote the famous *Syngramma Sacrum* (1525) He was a writer of great ability and popularity One of his teachings was that the body of the Lord is everywhere present, hence his followers were called "Ubiquitarians" Contrary to the usual opinions of the time Brenz did not favor the killing of Anabaptists and other heretics who did not belong to his party His works appeared in 8 vols at Tübingen (1576-90) Consult his life by Hartmann and Jäger (2 vols, Hamburg, 1840-42), and Kohler, *Bibliographia Brenziana* (Berlin, 1902)

BRERA, brá'ra (brera for bréda, from Lat. *prædium*, the estate, manor) The Palace of Science, Letters, and Arts in Milan It was erected by Richini for a Jesuit college in 1651 It contains a library of 300,000 volumes (founded in 1770), a collection of 50,000 coins, a magnificent collection of paintings (confined chiefly to Italian artists, however), an archaeological museum, and a good collection of casts from antique works In its courtyard stands Canova's bronze of Napoleon I as Roman Emperor

BRESCIA, brě'sha (anciently, Lat. *Briata*, founded by the Etruscans). An episcopal city of Lombardy, Italy (Map: Italy, E 2), capital of the province of Brescia, 52 miles east of Milan. It is situated in a fertile plain at the foot of the Alps, on the Mella and the Garza, and is dominated by a citadel known as the *Falcoma d'Italia*, that overlooks it from the rocky steepes on the north. Of the 65 churches that prospered at the time of the Venetian Republic, less than half are used for worship to-day. The old cathedral generally called *La Rotonda*, from its massive dome structure, dates partly from the ninth century, partly from the twelfth. The new cathedral, begun in 1604, but not completed until the nineteenth century, is one of the best examples of seventeenth-century architecture. The magnificent city hall, called *La Loggia*, the exterior of which is covered with ornamentation, was begun in 1489, on the ruins of a temple of Vulcan. The *Broletto* is a massive twelfth-century building, once the city hall, but now containing the courts of justice.

The Roman museum occupies a Corinthian temple excavated in 1822 and originally erected by Vespasian in 72 A.D. It is exceedingly picturesque and contains many valuable Roman antiquities. The Medieval Museum also contains numerous treasures. In the Palazzo Tozio, bequeathed to the town by Count Tozio, and in the Palazzo Martinengo, are important collections of ancient and modern paintings, engravings, and statuary. The library, bequeathed to the town in 1760 by Cardinal Quirini, has over 100,000 bound volumes and 1500 manuscripts, among them a ninth-century Book of the Gospels, a tenth-century Harmony of the Gospels by Eusebius, and a Dante manuscript. The number of works in the town, both *in fresco* and in oils, by Alessandro Bonvicino, called *Il Morretto*, is accounted for by the fact that he was born and passed most of his life in Brescia.

The city has many charitable institutions, a street railway, a theatre, a lyceum, several gymnasia, botanical gardens, and various academics, among them the *Accademia de' Filarmenici*, which is one of the oldest in Italy. Water from Membiano is distributed by an aqueduct to 72 public and 400 private fountains. There are factories for the manufacture of iron, one of the government works for small arms being here located; also mills for the spinning, weaving, and working up of silk, flax, cotton, and wool. There are also oil and paper factories. The trade in all these articles, and in wine, particularly *vino santo*, is very extensive, and there is a large general commerce, Brescia being a centre of transportation by both rail and highway. Pop. (communal), 1894, 67,700; 1901, 70,614; census of June 10, 1911, 83,338. The Celtic inhabitants of the ancient Brixia were allied with the Romans when Hannibal crossed the Alps. Under Cusar it became a Roman town; it was destroyed by the Huns, but soon rebuilt, and afterward passed through the hands of the Ostrogoths, the Lombards, Charlemagne, and the Germans. It was a leader among the Lombard cities which opposed Frederick Barbarossa, and in 1428 it came into the possession of Venice. At the beginning of the sixteenth century Brescia was one of the wealthiest cities of Lombardy; but it never recovered its former importance after being sacked and burned in 1512 by the French under Gaston de Foix. In

the rising of 1848 against Austria the citizens of Brescia took an active part, and after the battle of Custoza and the capitulation of Milan, shared the fate of other Lombard cities. In March, 1849, it was the only large city of Lombardy which rebelled, and, after the defeat of the Piedmontese at Novara, was bombarded and taken by Haynau and had to pay an indemnity of over \$1,200,000. In the War of 1859 it stood again by the side of Piedmont, and in 1860, with the rest of Lombardy, became a part of the Kingdom of Italy.

BRESLAU, brě'slon (Pol. *Wrocław*, also *Wratislavia*, *Bracław*, ML. *Wratislavia*, from King Wracislaw or Wratislaw). The capital of the province of Silesia, Prussia, and third royal residence, situated at the confluence of the Ohlau and Oder, 202 miles by rail southeast of Berlin, in lat. 51° 7' N. and long. 17° 2' E. (Map: Prussia, G 3). The Oder divides it into two parts, which are connected by numerous handsome bridges. It consists of the inner or main town and five suburbs, called the Ohlau, Sand, Oder, Nikolai, and Schweidnitz suburbs. The ancient fortifications have been converted into beautiful promenades, and the moat has been transformed into an ornamental sheet of water. The streets of the new portion of Breslau are spacious and regular, and the houses stately and handsome, affording a pleasant contrast to the sombre, massive structures and narrow streets of the old town. The city has many churches, the most remarkable being the Protestant church founded in 1250 and dedicated to St. Elizabeth, with a steeple 300 feet in height (the highest in Prussia), and a splendid organ, and the Roman Catholic cathedral, founded in 1148, containing many works of art in sculpture and painting. Among the other churches should be mentioned the church of the Holy Cross (thirteenth and fourteenth centuries), the church of St. Mary Magdalen (fourteenth century), the church of St. Michael (1871), and the fine synagogue. Other noteworthy buildings are the town hall (*Rathaus*), begun in the fourteenth century and lately restored; the university (1728-36), the civic hall (*Stadthaus*), and the government offices. Breslau is the largest city of Prussia, after Berlin and Cologne, which in 1910 surpassed it by less than 2500. Its proximity to the Russian frontier makes it a highly important trading centre in raw products. It holds three annual fairs, besides a number of special markets, e.g., in leather, horses, and cattle. Its position in the centre of manufacturing districts, and its railway connections with all the important cities, in addition to the facilities of communication which the Oder affords, increase still further its commercial importance. It has manufactories of linen, woollens, cotton, silks, lace, jewelry, metal wares and machinery, earthenware, soap, alum, starch, etc., and upward of 100 distilleries, and a trade in corn, coal, metals, timber, hemp, and flax. The city has a municipal council of 102 members, who elect an executive board of 27 for the practical administration of the municipal affairs. (See PRUSSIA, *Local Government*.) The municipality owns and operates two gas and two electric lighting plants, supplying all public and private buildings. The water works are also in the hands of the municipality. The street railways are private undertakings. Breslau has an excellent system of sewerage and sewage farms, on the general plan of those of Berlin, which

have proved so successful. Educational institutions are numerous and include a university (founded 1702) with a library containing over 312,000 volumes, six high schools (three belonging to the city), a good system of public elementary schools, a municipal library of 150,000 volumes, and two museums. The city is richly provided with hospitals and charitable institutions. In addition to the university clinic, there are two hospitals and an asylum under municipal control, as well as four orphan asylums. About 60 per cent of the inhabitants are Protestants, and about 35 per cent Roman Catholics. The population in 1910 was 512,105, as compared with 470,751 in 1905, 335,186 in 1890, 272,912 in 1880, and 171,926 in 1867.

Breslau is a city of Polish origin. In the thirteenth century it was an important Silesian city. It passed from the suzerainty of Poland in 1235 to Bohemia and in 1527 to Austria, from which it was taken by Frederick II of Prussia in 1741. Sixteen years afterward it was captured by the Austrians, after a bloody battle, but was retaken by Frederick in about a month. In 1807 it surrendered to the French. Soon after its fortifications were demolished. Here was issued in 1813 the proclamation by which Prussia entered the War of Liberation against Napoleon and it was vitally concerned in the Leipzig campaign. Consult Korn, *Breslauer Urkundenbuch* (Breslau, 1870), Städe, *Breslau* (Hamburg, 1895), Wutke, *Die Breslauer Messe* (Hamburg, 1895).

BRESSANI, brēs'sānē, FRANCESCO GIUSEPPE (1612-72). An Italian Jesuit missionary among the Indians of Canada. In 1644 he was sent to the Huron country, but was captured and tortured by the Iroquois. After great suffering he was sent to the Dutch settlements at Fort Orange (Albany), whence he was ransomed for a large sum. He returned to France, but came back to resume his missionary work in 1645 and labored among the Hurons until 1650, when, broken in health, he returned to Italy. He published *Relazione dei missionari della compagnia dei Gesuiti nella Nuova Francia* (1653), a French translation of which appeared in Montreal in 152, Eng trans in Thwaites, *Jesuit Relations*, especially vols xxxviii, xxxix, xl (Cleveland, 1898).

BRESSAY, brēs'sā. One of the Shetland Islands (qv), Scotland, east of Mainland, separated from Lerwick by Bressay Sound (Map Scotland, G 1). Area, 12 square miles. It supplies the Shetland Islands with slates. The population in 1911 numbered 641, and fishing is the chief occupation. East of Bressay, separated by a narrow and dangerous sound, is the most remarkable of Shetland rock phenomena, an islet called Ness, surrounded by perpendicular cliffs 300 to 500 feet high, culminating in the Noup, a fine peaked headland 600 feet high. Bressay and Ness are important breeding grounds for Shetland ponies.

BRESSLAU, brēs'lau, HARRY (1848-). A German historian. He was born at Dannenberg, Hanover, and studied history at the universities of Göttingen and Berlin. In 1870 he was appointed teacher at the *Realschule* of the Jewish congregation in Frankfurt-on-the-Main, where he remained until 1872, when he was called to the Andreas Realschule at Berlin, in the same capacity. Simultaneously he became private lecturer at the Berlin University and was appointed extraordinary professor at that uni-

versity in 1877. He was appointed a member of the central directorate of the Monumenta Germaniae Historica in 1888, and also became editor (1888-1903) of the *Neues Archiv der Gesellschaft für ältere deutsche Geschichtskunde*. His appointment to the chair of history at Strassburg came in 1890, and from 1904 to 1905 he was rector of the university. Among his numerous publications are the following: *Diplomata Centum* (1872), *Jahrbücher des deutschen Reichs unter Kaiser Heinrich II*, vol II (1875), *Jahrbücher des deutschen Reichs unter Konrad II* (2 vols, 1879-84), *Zur Judenfrage, Sendschreiben an Heinrich von Treitschke* (2d ed., 1880), *Handbuch der Urkundenlehre*, vol I (1889, 2d ed., 1912), *Das Tausendjährige Jubiläum der deutschen Selbständigkeit* (1912).

BREST (anciently, Lat *Gessoriate*, according to others, *Gessorivates*, or *Bivates Portus*). A strongly fortified seaport of Brittany, France, in the department of Finistère, at the mouth of the Penfeld, on the Bay of Brest, 389 miles west of Paris by rail (Map France, N, A 4). Le Goulet, the entrance to the bay, scarcely a mile wide, is protected by powerful batteries. The harbor, one of the chief naval stations of France, contains military and naval ports, fully equipped with floating and graving docks, quays, piers, and a breakwater, completed in 1876 at a cost of 22,500,000 francs (\$4,500,000). A modernized citadel, whose foundations date from the thirteenth century, dominates the city and harbor, which are also protected by batteries. The city itself is old, duty, and has steep, crooked streets. The public institutions consist of a botanical garden, lyceum, naval schools, naval library, marine and civil hospitals, and a free library. The Cours Dajot, a beautifully wooded promenade, overlooks the commercial port and breakwater. It has an active trade in wine, coal, timber, tar, fertilizers, and shell food as imports, and flour, fruit, and vegetables as exports. The industries are sardine and mackerel fishing, mills, foundries, engineering works, breweries, and manufacturing of candles, chemicals, boots, shoes, and linen. Brest has submarine telegraphic communication with the United States, which is represented by a consular agent. Brest came into national importance when it was converted into a great fortress by Vauban towards the close of the seventeenth century. Since then it has been considerably strengthened. The population consists largely of naval and seafaring people. Pop., 1906, 85,204, 1911, 90,540. Consult *L'Annuaire historique et statistique de Brest* (Brest, 1899), Kernér's, "Contribution à l'histoire de la ville et du port de Brest" in *Soc Académique de Brest Bull* (Brest, 1910-12).

BREST-LITOVSK, brēs't/lyā-tōfēsk' (Russ., Lith. *Brest*, Pol. *Breść-Litewski*, anciently *Berestyc*, *Berestow*, 'the elm city,' from *berestā*, elm). A first-class fortress and the capital of a district in the government of Grodno, Russia, situated 131 miles south of Grodno, at the junction of the Mukhavetz and the Bug (Map Russia, B 4). Pop., 1908, 47,604, including 27,000 Jews. Brest-Litovsk, one of the oldest Slav towns, belonged to Poland till 1795. At the Church congresses held here in 1590, 1594, and 1596, the union of the Eastern and Western churches, recognizing the supremacy of the Pope, but retaining the Eastern ritual and the Slavonic language in worship, was proclaimed, notwith-

standing the protests of the Russian and Greek representatives. It is the seat of Armenian and Greek Catholic bishoprics. Although but little manufacturing is carried on, the town is of considerable commercial importance, situated as it is on the inland water way from the Baltic to the Black Sea, and at the intersection of the railroads connecting Odessa with Königsberg and Moscow with Warsaw. There is trade in grain, leather, hemp, flax, and wood. Two fairs are held annually.

BRETAGNE, *bre-tā'ny*. See **BRITTANY**.

BRETEUIL, *bre-tē'y*, LOUIS CHARLES AUGUSTE LE TONNELIER, BARON DE PREUILLY (1733-1807). A French diplomat and statesman. He was appointed, in 1758, after several years of military service, envoy to the Elector of Cologne, and Minister to Sweden in 1769. Subsequently he was also Minister at Vienna and Naples. In 1783-87 he was Minister of State, a steadfast royalist, opposed to all concessions to the Third Estate. In 1789 he was appointed to succeed Neckar, but his ministry was brought speedily to a termination by the capture of the Bastille. Having counseled the King to escape across the frontier and seek foreign aid, he himself withdrew to Solothurn, Switzerland, where he was appointed royal agent to treat with foreign powers regarding the restoration of the monarchy. In 1802 he was permitted to return to France, but thenceforth took no part in politics.

BRETHREN, BOHEMIAN. The name of a religious society which was first instituted in Bohemia about the middle of the fifteenth century. It was originally composed of remnants of the Hussites. Dissatisfied with the conduct of the Calixtines (see **HUSSITES**) they went, in 1453, to the borders of Silesia and Moravia, where they settled. Here they dwelt in separate communities and were called Brothers of the Rule of Christ. Their adversaries often confounded them with the Waldenses and Picards, while, on account of their being compelled during persecutions to hide in caves and solitary places, they were also called cave dwellers (*Grubenheimer*). In spite of oppression, such was the constancy of their faith and purity of their morals that they became profoundly respected, and their numbers greatly increased. The chief peculiarity of their creed was the denial of the Catholic doctrine of transubstantiation; but they rejected tradition generally, and professed to found their tenets only on the Bible. Their ecclesiastical constitution and discipline—of which the Lutheran reformers spoke highly—was a close imitation of that of the primitive Christian communities. Under the conviction that religion should consciously penetrate and characterize the entire life of men, they extended ecclesiastical authority over even the details of domestic life. Their chief functionaries were bishops, seniors and consensors, presbyters or preachers, adiles, and acolytes. The nucleus of the sect was the following of Peter Chelozicky, a layman of the nobility. To them Rokyzana, the Utraquist leader, sent Gregor in 1457, and he led them when persecution broke out to Kunwald, in Bohemia, near Königgrätz, whence, however, they were driven to the mountains. Gregor died in 1474. Their next great man was Luke of Prague, who brought them into literary contact with the Waldenses. The latter translated some of their writings, and these translations have frequently been taken for original Waldensian works; for the Bohemian Brethren had

literary intercourse with the Waldenses, but the differences between them prevented union. They had also ecclesiastical connection, for their bishop, Matthias of Kunwald, was consecrated by a bishop of the Bohemian Waldenses. It was against their principles to engage in war; and having on several occasions refused to take up arms, they were at last deprived of their religious privileges. The result was that in 1548 about 1000 of the Brethren removed to Poland and Prussia. The contract which these exiles entered into with the Polish reformers at Sandomir, April 14, 1570, and still more the religious peace concluded by the Polish States in 1572, secured their toleration; but subsequently, in consequence of the persecutions of King Sigismund III., they united themselves more closely to the Protestants, though even at the present day they retain something of their old ecclesiastical constitution. The Brethren who remained in Bohemia and Moravia obtained a little freedom under the Emperor Maximilian II and had their chief seat at Fulnek, in Moravia. In the seventeenth century a number removed into Hungary, but during the reign of Maria Theresa were coerced into Catholicism. The Thirty Years' War, so disastrous to the Bohemian Protestants, entirely broke up the societies of the Bohemian Brethren; but afterward they united again, though in secrecy. Their exodus about 1722 occasioned the formation, in Lusatia, of the *United Brethren*, or *Herrnhuters*. See **MORAVIANS**.

BRETHREN, PLYMOUTH. See **PLYMOUTH BRETHREN**.

BRETHREN, WHITE. A sect of the fifteenth century, that sprang up in the Italian Alps. Their leader claimed to be Elias the prophet. They were clad in white and carried crucifixes from which blood appeared to come. The leader, who appears to have left no name, prophesied the destruction of the world and for a time had great success; but Boniface IX seized the prophet and burned him at the stake, and within a year the sect passed out of existence.

BRETHREN OF THE LORD, THE (Gk. *ἀδελφοὶ τοῦ Κυρίου*, *adelphoi tou Kyriou*). A term which occurs but once in the New Testament (1 Cor. ix. 5), though the phrase "the Lord's brother" is applied once to James (Gal. i. 19), and the general term "his (my) brethren" is used several times in the Gospels (Mark iii. 31; Matt. xii. 46, 50; xxviii. 10, John ii. 12, vii. 3, 5, 10; xx. 17) and once in Acts (i. 14).

In view of these passages that refer apparently to actual brothers and sisters of Jesus, giving the names of the former as James and Joscs (Joseph) and Judas and Simon (Mark vi. 3 and Matt. xiii. 55), there has existed, ever since the Patristic age, considerable controversy regarding the degree of consanguinity involved in the above term.

Three views have obtained: 1. The Helvidian—first asserted by Tertullian (c.208 A.D.) and restated by Helvidius (c.380 A.D.)—that these brethren were later sons of Mary by Joseph, the reputed father of Jesus. 2. The Epiphonian—first appearing in the second century apocryphal books, the Gospel of Peter, and the Protevangelium of James, and chiefly supported by Epiphanius (c.370 A.D.)—that these brethren were sons of Joseph by a former marriage. 3. The Hieronymian—promulgated by Jerome (c.380 A.D.)—that these brethren were cousins

of Jesus, being sons of Alphæus (Clopas), the husband of a sister of Mary.

Of these views, the first is fatal to, while the latter two sustain, the theory of the perpetual virginity of Mary. The last view is generally rejected by modern scholars, as between the first and the second views the scholarship of today is practically balanced. Consult for the first view, J. B. Mayor, Introduction to his *Commentary on James* (1897), for the second view, J. B. Lightfoot, Excursus in his *Commentary on Galatians* (1887), for the third view, Mill, *The Accounts of our Lord's Brethren* (1843). See JAMES.

BRETIGNY, bré-tî-nî' A village of France, in the department of Eure-et-Loir, about 6 miles southeast of Chartres, on the railway between Paris and Orleans. At Bretigny, on May 8, 1360, Edward III. concluded a treaty with France, by which the French King, John II, was released from captivity in England, on agreeing to pay 3,000,000 ecus of gold (about \$8,000,000) for his ransom. Edward renounced his pretensions to the crown of France, his title to Normandy, Anjou, Maine, and Touraine, and the suzerainty over Brittany and Flanders, but was confined in his possession of Guenne and Gascony, and received in addition Poitou, Saintonge, Calais, and a number of other places. See FRANCE, and consult LAVISSE, *Histoire de France*, vol. IV, part 1, pp. 161-166 (Paris, 1902).

BRETON, bré-tôn', GILLES LE (?-1550) A French architect. He was employed in the work of transforming the old conventual buildings at Fontainebleau (qv) into a palace. There is some doubt as to his exact functions, but Palustré attributes to him the design of the Cour Ovale, Porte Dorée, both chapels (Trinité and St. Saturnin), and the Galerie Henri II, making him thus the author of the most interesting parts of the palace before the time of Henri IV. He died in 1550, during the reign of Henri II.

BRETON, JULES ADOLPHE (1827-1906) A French figure painter of peasant subjects, also an author of note. He was born at Courrières (Pas-de-Calais), and studied under Devigné at Ghent, Wappers at Antwerp, and Drolling at Paris. Beginning as an historical painter, he soon found his forte in depicting the life and surroundings of the peasants of his native Artois and later of Brittany. Breton's art occupies a middle position between French classic tradition and the poetic realism of a Millet. He is greatest in landscape. Although his figures are not free from a certain academic pose, and both figures and landscape lack rugged strength, he charms by the tender sentiment of his works. Among his principal ones are "Blessing the Grain" (1857), and, most celebrated of all, the "Return of the Gleaners" (1869), both in the Luxembourg, Paris. "Planting a Calvary" (1859, Lille), "Women Weeding" (1861), "The Potato Harvest" (1868), "At the Fountain" (1872, Quimper), "The Reaper" (1877, Luxembourg), "The First Communion" (1881), "Song of the Lark" (1885, Art Institute, Chicago), "The Pardon of Kergoat" (1891, Metropolitan Museum, New York), "Twilight Glory" (1900), "Love and the Wild Lily" (1905). An author of note, he wrote poetry and prose with equal facility, his literary works including *Les champs et la mer*, poems (1875), *Jeanne*, a poem (1876), *La vie*

d'un artiste (1890) and *Un peintre paysan* (1895), the last two autobiographical in character. He received many medals and was a commander of the Legion of Honor (1889). Consult besides the works cited above, Vachon, *Jules Breton* (Paris, 1899), Monod in *Art et décoration* (ib., 1906).

BRETÓN DE LOS HERREROS, bré-tôn' dâ lôs a-r-ré-rôs, DON MANUEL (1796-1873) A popular Spanish poet and dramatist. He was born at Quel, in the province of Logroño, was educated in Madrid, and after eight years of military service held several positions under the government, but always lost them on account of his free expressions of liberal opinion. His first essay in the drama was *La vejez vueela*, which in 1824 was produced with great success. Other plays followed in rapid succession, numbering altogether more than 150, partly original, partly adaptations from earlier Spanish classics, and partly translations from the Italian and French, some of which were very popular. They form a history of Spanish customs during the first half of the nineteenth century. The appearance of his comedy *Marcela* (1831) was the beginning of the invasion of romanticism into Spanish dramatic art. His own favorite among his dramas was *Muñete y verdades*, which appeared in 1837, the year of his election to the Royal Spanish Academy, whose secretary he became later. His best and most ambitious play is the *Escuela del matrimonio* (1852), an admirable picture of average Spanish social life, with just the needed touch of irony to relieve it. His lyrical and satirical poems please by their elegance, vivacity, and piquancy. Had he been content to write less, he might have left a more enduring fame. His collected works, edited by himself, appeared in Madrid (1850-52) in 5 vols. A better edition is that of Bretón y Orozco (5 vols., Madrid, 1883). His *Obras Escogidas*, selected by himself, appeared in 2 vols., in Paris, shortly after the aforesaid Madrid edition of 1850-52. For a detailed study by an intimate friend, consult the Marqués de Molins, *Bretón de los Herreros* (Madrid, 1883). Consult Pifeyro, *El Romanticismo en España*, *Le Gentil*, *Le poète Manuel Bretón de los Herreros et la société espagnole de 1830 à 1860* (Paris, 1909).

BRETON LITERATURE The Breton, or Armorican, language belongs to the British subdivision of the Celtic family of languages (See CELTIC LANGUAGES). In its earliest form it was spoken in Britain and closely resembled Cornish. As a result of social and political disturbances in Britain, many of the Celtic inhabitants emigrated during the fifth and sixth centuries to what is now French Brittany. The language that they planted there was known as Breton or Armorican. Besides certain linguistic peculiarities, such as the tendency to introduce parasitic nasals, Breton is distinguished from Welsh and Cornish by the large number of French words that it has naturalized from the time of Anne de Bretagne to the present day. The Celtic language was entirely driven out of Upper Brittany by French, but in Lower Brittany it is still spoken by more than a million people. In modern Breton four distinct dialects are recognized—those of Léon, Tréguier, Cornouailles, and Vannes. The Vannetais stands rather apart from the other three.

The material for the study of Old Breton consists entirely of glosses, containing some 500

different words, and lists of proper names, of which there is a considerable quantity in manuscripts ranging from the eighth to the tenth century. The oldest literary monuments that have been preserved are Middle Breton, from the fourteenth century on, and like those in Cornish they are almost entirely of a religious character. A number of the most important texts are accessible in recent editions.

During the nineteenth century there was a kind of literary revival in Brittany. In 1827 the Bible was translated into Breton by Le Gonidec. In 1839 appeared the first edition of *Barzaz Breiz*, by de Villemarqué, a book which gave rise to a long discussion resembling, on a smaller scale, the controversy over Macpherson's *Ossian*. The *Barzaz Breiz* was finally discredited as a reproduction of Breton popular songs, but it gave an impulse to the work of more scientific collecting which has gone on steadily to this day. The most valuable publications in this field have been those of M. F. M. Luzel.

At the present time in Brittany, as in the other Celtic countries, an active effort is being made to preserve the native language and to promote its use in literature.

Bibliography. For Old and Middle Breton monuments consult: Loth, *Chrestomathie Bretonne* (Paris, 1890); Ernault, *Le Mystère de Saints Barbe* (Paris, 1888); *Glossaire moyen-breton* (Paris, 1895-96). An important bibliography of modern Breton materials was contributed by Gaidoz and Sebillot to the *Revue Celtique*, vol. v (Paris, 1875); Henry, *Lexique étymologique du Breton moderne* (Rennes, 1900) is a very useful etymological dictionary. For history and criticism of Breton literature consult Le Goffic, *L'âme bretonne*, vols. i, ii (Paris, 1908-12). The current magazine *Les Annales de Bretagne* usually contains valuable contributions and bibliographies. Consult also Leclerc, *Grammaire bretonne* (Paris, 1908).

BRETSCHNEIDER, brät'shni-dër, HEINRICH GOTTFRIED VON (1739-1810). An Austrian author of somewhat eccentric habits. He was born at Gera and was educated first at the Institute of the Moravian Brothers at Elbersdorf and afterward at the gymnasium at Gera. He became captain of horse in a Prussian volunteer corps, in which service he was taken prisoner and was confined in a French fort until 1763. In 1775 he visited England, France, and Holland; in 1776 he entered the service of the Austrian government and in 1778 was nominated librarian of the University of Budapest, where through his eccentricities he came in conflict with the Jesuits. Emperor Joseph II undertook to protect him from their attacks. He was the author of many tales, poems, and satires, most of which appeared anonymously. The latter are attacks upon every kind of injustice and falsehood. In his *Almanach der Saints* (*Almanach der Heiligen*), for the year 1788, the priesthood is severely attacked, and the legends of the monks ridiculed.

BRETSCHNEIDER, KARL GOTTFRIED (1776-1848). A German Protestant theologian. He was born at Gersdorf, Saxony; studied at the University of Leipzig; was a lecturer on philosophy and theology at Wittenberg from 1804 to 1806; and in 1807 became pastor at Schneeberg. In 1816 he was appointed superintendent general and a member of the supreme consistorial court at Göttingen. He was a representative of the school of so-called rational supranaturalism, whose in-

termediate position is indicated by its name. His many and varied works display scholarly acuteness and literary skill, but lack speculative depth. His *Probabilia de Evangelii et Epistolarum Joannis Apostoli Indole et Origine* (1820) aroused considerable controversy. He is best known for the *Systematische Entwicklung aller in der Dogmatik vorkommenden Begriffe* (1805, 4th ed., 1841); and in particular for the *Lexicon Manuale Jacco-Latinum in Libros Novæ Testamenti* (2 vols., 1824, 3d ed., 1840). He established the *Corpus Reformatorum* (Halle, 1834 et seq.) and from 1832 was editor of the *Allgemeine Kirchenzeitung* of Darmstadt. A part of his autobiography (1851) is to be found translated in *Bibliotheca Sacra*, vols. ix and x.

BRETT, WILLIAM BALIOL. See ESHER, WILLIAM BALIOL BRETT, first Viscount.

BRET'TEN (in the eighth century, *Bredaheim*). A town of Baden, on the Saalbach, about 13 miles east of Karlsruhe, celebrated as the birthplace of Melancthon, the "Praeceptor Germaniae." It has manufactories of machinery and jannaped goods and carries on a trade in timber and cattle. Pop., 1900, 4800; 1910, 6025.

BRETTON, HENRY DE. A variant of BRAC-TON.

BRETT'S AND SCOTS, THE LAWS OF THE. The name given, in the thirteenth century, to a code of primitive law in use among the Celtic tribes in Scotland. The "Scots" were the Celtic people dwelling in the western and more mountainous districts north of the Forth and the Clyde, who, when it became necessary to distinguish them from the Teutonic inhabitants of the low country, received the names of "the wild Scots," and, more recently, "the Scotch Highlanders." The "Bretts" were the British or Welsh inhabitants of the region lying south of the Forth and Clyde. This province was for some centuries an independent kingdom, known by the names of "Cumbria," "Cumbria," and "Strathclyde." It became, about the middle of the tenth century, a tributary principality held of the King of the English by the heir apparent of the King of the Scots. It so continued till after the beginning of the twelfth century, when, Cumberland having been incorporated with England, the gradual absorption of the rest of the territory into the dominions of the King of the Scots seems to have been imperceptibly completed.

No more is heard of Cumbria as a principality, but "the Welsh" continue to be named among its inhabitants, in the charters of the Scotch kings, and they seem to have retained more or less of their ancient Celtic laws until after the beginning of the fourteenth century. It was not till the year 1305 that an ordinance of King Edward I of England, who appeared then to have reduced all Scotland to his subjection, decreed "that the usages of the Scots and the Bretts be abolished, and no more used." It is unknown how far this prohibition took effect. Of the code which it proscribed only a fragment has been preserved. The best citation is that preserved in the *Acts of the Parliaments of Scotland*, vol. i, pp. 299-301 (Edinburgh, 1844), where the laws are given in three languages—Latin, French, and English. The French version, which is the oldest, is printed from a manuscript of about 1270, now in the register house in Edinburgh. The fragment of the "laws of the Bretts and the Scots" thus published is

of much the same nature as the ancient laws of the Anglo-Saxons, the Welsh, the Irish, and other nations of western Europe. They are principally concerned with crimes of violence and contain elaborate provisions for determining the penalty of such crimes and the terms on which they might be commuted. They fix the *cro* or price at which every man was valued, according to his degree, from the king down to the churl, and which, if he were slain, was to be paid to his kindred by the homicide or his kindred. The *cro* of the king was 1000 cows, of the king's son or of an earl, 150 cows, of an earl's son or of a thane, 100 cows, of a thane's son, 66⅔ cows, of the nephew of a thane, or of an oghthein, 44 cows and 21⅓ pence, and of a villen or churl, 16 cows—all persons of lower birth than a thane's nephew, or an oghthein, being accounted villens or churls. A chapter "of blood-drawing"—corresponding with the *blodwyte* of the Anglo-Saxons—fixes the fine for a blow to the effusion of blood according to the degree of the person wounded and the place of the wound. See BLOOD FEUD, BLOOD MONEY, BREHON LAWS, WERGILD.

BREUGEL, bré'kel (BREUGHTEL) A family of Dutch painters. See BRUEGEL.

BREUL, biol, KARL IERMAN (1860—) A German-English scholar. He was born in Hanover. He studied from 1878 to 1883 at the universities of Tübingen, Strassburg, and Berlin, and in 1884 was appointed lecturer in German at the University of Cambridge. In 1885 he was also appointed lecturer in German at Girton and Newnham colleges. He was acting president and honorary vice president of the Modern Language Association in 1907, examiner to the universities of Oxford and Cambridge, to London University, and to the Royal University of Ireland, in 1897 became subeditor of the *Modern Quarterly of Languages and Literature*, and in 1910 was chosen professor of German in the University of Cambridge. He is among those who seek to introduce into England the educational methods of Germany. His publications include editions of (1889) Hauff's *Das Bild des Kaisers* (1890), Schiller's *Wilhelm Tell*, and (1899) Goethe's *Iphigenie a Handy Bibliographical Guide to the Study of the German Language and Literature* (1895), *Das höhere Schulwesen Grossbritanniens* (1897), *The Teaching of Modern Languages and the Training of Teachers* (3d ed., 1906). He also revised Heath's *German and English Dictionary* in 1906 and again in 1910, and prepared the bibliography for Goethe's *Poetry and Truth*, trans. by Muma Smith (London, 1913).

BREVE, brév (It *breve*, from Lat *brevis*, short). In general, a short writ, or royal mandate or summons. Specifically, in the practice of the Scottish law, since the institution of the Court of Session (1532), a writ issuing out of chancery in the name of the crown, to a judge, authorizing and directing him to try by jury the allegations of fact contained in the writ. Formerly these *breves*—corresponding to the *writs* and *pleas* of English legal procedure—were the foundation of almost all civil actions in Scotland, but with a simplified procedure they have gradually fallen into desuetude. They are retained, however, in a limited number of special proceedings, as in the appointment of a guardian to a minor or a lunatic, in the partition of an inheritance among several heirs, and in proceedings on the part of a widow

to recover her dower. See CHANCERY, PLEA, WRIT.

BREVE (It from Lat *brevis*, short). A note in music, found in early ecclesiastical notation, having the value of two whole notes or semibreves. In the measured strains of the old church music melodies moved slowly. About the eleventh century the two principal notes, in use were the *longa*, , and the *brevis*, , the first being twice or three times the length of the second, according to the measure used. So the *brevis*, or *breve*, the longest note possible in modern notation, was then considered a "short" note, as its name implies. At that time all notes were black, or "filled in." When, in the fifteenth century, white or "open" notes came into use, the *breve* was printed and still later . Either of these later forms is used in the rare instances when it is introduced into modern music. See MEASURABLE MUSIC.

BREVET (OF *brevet*, Fr *brevet*, dim of *bref*, from Lat *brevis*, short, the commission being a brief writing). A military commission endowing its recipient with a higher rank and title than he would otherwise be entitled to, or than that for which he draws pay. In French usage it applies to commissions in general. In England and the United States it has particular application to a special or higher commission, which is conferred as a mark of distinction, but which does not carry with it any increase in pay. In the United States such officers are addressed unofficially by their *brevet* rank, but in England such is the case only by courtesy, while officially both titles are used, as, for example, "Major and Brevet Lieutenant Colonel Smith." Originally the term designated a promotion given on such occasions as a coronation, or the termination of a great war, and had its origin during the reign of James II (1685-88), but it was abused so frequently and to such an extent by the general award of *brevet* commissions, that in 1854, during and after the Crimean War, its bestowal was limited strictly to cases of very distinguished service in the field and on the principle of seniority. A regimental officer holding a *brevet* rank takes the precedence due his rank only when in the field, for regimental purposes he ranks according to his regimental seniority. In the United States *brevet* titles were given during the Indian, Civil, and Spanish wars for "conspicuous gallantry," "gallant and meritorious service," etc, but they have only honorary significance. Officers who receive such commissions are recommended to the President, who nominates them and sends the commissions to the Senate for confirmation. *Brevet* commissions range in rank from first lieutenant to lieutenant general. In England *brevet* commissions are confined to grades not lower than the rank of captain or higher than lieutenant colonel.

BREVIARIUM OF EUTHYPIUS. See EUTHYPIUS.

BREVIARY (Lat *brevarium*, abridgment, abstract, from *brevis*, brief, short). The book, among Roman Catholics, which contains what is called the "divine office," or the service for the canonical hours. From very early Christian times the regular recitation of the Psalms of David formed a large part of the public and private devotion, it was developed in the West by the monks, whose life included frequent meeting for prayer, and still forms the ground-

work or nucleus of these offices. Around it grew up a whole system of hymns, prayers, antiphons (q.v.), responses, and readings from Holy Scripture, which forms a very varied and complicated service. Before the sixteenth century there was an infinite number of local uses, nearly every diocese having its own breviary. The most ancient and liturgically important of the non-Roman breviaries are the Mozarabic, once general throughout Spain, and the Ambrosian, traditional in Milan from the days of St. Ambrose. Pope Pius V abolished all that could not show an antiquity of 200 years; and at the present day the Roman breviary is almost universally used, with the exception of some slight calendar variations among the religious orders. It was systematized by Gregory VII (1073-85), received its practically final form under Pius V in 1568, with subsequent revision in detail by Clement VIII (1602) and Urban VIII (1634), and additions of new offices and feasts by all the later popes. The great number of new saints' days has rendered the ordinary ferial or week-day office very uncommon; and Leo XIII in 1883 permitted the substitution for it, on days when it would naturally occur, of a "votive" or voluntary office of a festival character, differing according to the days of the week. There is a tendency in favor of shortening the office, whose recitation, even in private, occupies at least an hour and a half every day. So complicated has the system become that a sort of annual almanac, called *Ordo Recitandi Divini Officii*, is published in many countries, containing minute directions as to what is to be read. The need of simplification led Cardinal Quignon or Quinones, a Spaniard, to publish a reformed breviary in 1535, which, while it was never widely used, gave the English reformers a number of hints for their simplified and condensed prayer book (q.v.).

The canonical hours are seven: matins and lauds (forming practically one service), prime, terce, sext, none, vespers, and compline. Matins was supposed to be, and is in monasteries, sung in the night; the other offices are called the day hours, and are published in separate form, for convenience, under the title *Horæ Diurnæ*. Lauds and vespers are the most important of these services, containing the "evangelical canticles" (the *Benedictus* at lauds and the *Magnificat* at vespers) and being sung with more ritual solemnity. The names prime, terce, sext, and none refer to the times at which they were originally recited—the first, third, sixth, and ninth hours of the day. Compline (*completorium*, the completion of the cycle) was recited at bedtime. Those who recite them privately, however, do so at any convenient time and frequently join two or more offices together. The daily recitation of the breviary is strictly obligatory on all clerics and all "choir" members of religious orders (as distinguished from lay brothers or sisters). The use of the breviary as a book of private devotion by laymen has become rare since the multiplication of devotional works of different kinds, but at present shows some tendency to increase; and it has always been a common custom to sing vespers or compline, at least on Sundays, in parochial churches.

The contents of the breviary, after the general rubrics, tables, calendar, etc., fall into five parts: 1. The Psalter, or original arrangement of the Psalms and prayers for the days of the week.

2. The Proper of the Season, containing the service for Christmas, Easter, Pentecost, and the seasons dependent on them. 3. The Proper of Saints, for the numerous special feasts which recur on a fixed anniversary. 4. The Common of Saints, parts of the service which belong to classes of saints, as apostles, martyrs, confessors, etc. 5. Several minor services, including the office of the dead and the little office of the Blessed Virgin Mary. The breviary forms a marvelous storehouse of powerful and tender religious thought; and as by far the largest part of its contents is in the language of Scripture, it is invested with much grandeur and vitality, while the lessons from the fathers and the lives of the saints read at matins contain a mass of scriptural, historical, and theological knowledge. Consult: *The Roman Breviary* (an Eng. trans. by the Marquis of Bute (London, 1879; rev. ed., New York, 1910); Batiffol, *History of the Roman Breviary* (London, 1912); Fleitner, *Altlate Geschichte des Breviergebetes* (Kempter, 1887); Bäumer, *Geschichte des Breviers* (Freiburg, 1895); S. Baumer, *Histoire du Breviaire* (Paris, 1905). For a modern edition of Quignon's breviary, consult Legg (Cambridge, 1888).

BREVIARY OF ALARIC (*Breviarium Alaricum*). An important collection of Roman laws, compiled by order of Alaric II, King of the Visigoths, in the first decade of the sixth century A.D. It corresponds historically to the code of laws promulgated by Theodoric, King of the Ostrogoths (*Edictum Theodorici*), the Salic Law (*Lex Saliica*) and Riparian Law (*Lex Ripuaria*) of the Franks, and other similar codes of that period. The primitive conception of law, as of personal and not territorial application, compelled the barbarian invaders to administer two systems of law—one for their barbarian followers, and the other for the Roman inhabitants of the territory occupied by them. The Breviary of Alaric II was a code designed for the Roman subjects of the invader and was almost exclusively Roman in character. It was made up of extensive abridgments of the Code and Novels of Theodosius, the Institutes of Gaius, and other recognized authorities. These texts were accompanied by an elaborate commentary, called the *Interpretatio*. A corresponding code promulgated by Alaric for his barbarian subjects, and containing their own native law, was known as the *Forum Judicium* and *Judicium Liber*. This was of the character of other primitive codes, as the Anglo-Saxon laws, the ancient Brehon law of Ireland, etc., though tintured, more than these, with the influence of Rome. The two codes together constitute the *Lex Visigothorum*. (See CIVIL LAW.) Consult Lee, *Historical Jurisprudence* (New York, 1900). See ALARIC II.

BREVIARY. See PRINTING.

BREVOORT, JAMES RENWICK (1832-). An American landscape painter. He was born in Westchester Co., N. Y., and studied architecture under Renwick in New York and painting under Thomas Cummings. In 1863 he was elected a member of the National Academy and in 1872-75 was its professor of perspective. He then lived for six years in Italy and sketched extensively in Germany, Holland, and England. He belonged to the older school of American landscapists, who have stood aloof from modern technical advances. He treats such subjects as "Lago Maggiore," "November Winds," "Scene in

Holland, near Arnheim, ' Castle of Heidelberg—Sunset," 'On the Gulf of Salerno," "A Swiss Scene, "Morning in Early Winter," 'Wild November Comes at Last"

BREWER A city in Penobscot Co, Me, on the Penobscot River, opposite Bangor, with which it is connected by a bridge, and on two branches of the Maine Central Railroad (Map Maine, D 4) It has lumber, paper, and pulp mills, a tannery, brickyards, and shipbuilding yards Brewer was set off from Orrington, incorporated in 1812, and was chartered as a city in 1889 The government is administered by a mayor, elected annually, and a city council Pop., 1900, 4835, 1910, 5667 Consult *History of Penobscot County* (Cleveland, 1882)

BREWER, DAVID JOSIAH (1837-1910) A distinguished American jurist, born at Smyrna, Asia Minor He graduated at Yale in 1856, at the Albany Law School in 1858, in 1861 and 1862 was a United States Commissioner, and in 1862-65 was judge of the probate and criminal courts of Leavenworth Co, Kans In 1865-69 he was judge of the District Court of the First Kansas District and from 1870 to 1884 was a justice of the State Supreme Court After having served as judge of the Circuit Court of the United States in 1884-89 he was appointed, in 1889, an associate justice of the United States Supreme Court He was also appointed a member of the Venezuelan Boundary Commission in 1896 While on the State bench he gave an opinion sustaining the Maxwell land grant, the largest private grant sustained in the United States, and a dissenting opinion on the question of the power of a municipality to issue bonds in assistance of railways During his 21 years of service on the bench of the Supreme Court he attained a position of commanding influence on public opinion as well as upon the development of the public and private law of the United States He was ranked as a scholarly jurist, and his public addresses attracted favorable attention His publications include *The Pew for the Pulpit* (1897), *American Citizenship* (1902), *The Mission of the United States in the Cause of Peace* (1909)

BREWER, EBENEZER COBHAM (1810-97). An English author and clergyman of the Established church, born in London He was educated at Cambridge and in 1836 was ordained priest He wrote many educational books, but was known chiefly for his various compendia and reference works, which include *A Guide to Scientific Knowledge* (1850), *A Guide to Scripture History* (1860), *A Guide to Every-Day Knowledge* (1864), *A Dictionary of Phrase and Fable* (1870, 25th ed, 1894), *The Reader's Handbook of Allusions, References, Plots, and Stories* (1880, 12th ed, 1888), *A Historic Note-Book* (1890)

BREWER, JOHN HYATT (1856-) An American organist and composer, born in Brooklyn, N Y He studied under Dudley Buck and in 1881 was appointed organist of the Lafayette Avenue Presbyterian Church From 1899 to 1906 he was professor of vocal music in Adelphi College, and in 1903 he was elected leader of the Apollo Club, of Brooklyn, N Y His compositions include church music, and secular works for voice, organ, piano, and orchestra.

BREWER, JOHN STIERSEN (1810-79). An English historical writer, born in Norwich He was educated at Queen's College, Oxford, took deacon's orders in 1837, and in 1839 was ap-

pointed lecturer in classical literature at King's College, London In 1855 he was appointed professor of the English language and literature and lecturer in modern history For some time he was editor of the *Standard*, but in 1856 began for the Master of the Rolls a series of investigations for the preparation of various works, of which the *Calendar of Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII* (incomplete, vols 1-v, 1862-72) must be reckoned the most important His further works in this connection include editions of the *Monumenta Franciscana* (1858) and (1859) of the *Opus Tertius and Opus Minus* of Roger Bacon His *English Studies*, republished from the *Quarterly Review*, were edited by Dr Wace in 1881

BREWER, THOMAS MAYO (1814-80) An American ornithologist, born in Boston, Mass, Nov 21, 1814, and died there Jan 23, 1880 He was a physician, newspaper editor, and publisher In 1839 he edited a new edition of Wilson's *Ornithology* He wrote most of the biographical sketches in the *History of North American Birds*, by Baird, Brewer, and Ridgway (1874-84)

BREWER, WILLIAM HENRY (1828-1910) An American agriculturist, born in Poughkeepsie, N Y He graduated at Yale (now Sheffield) Scientific School, 1850, and was appointed professor of agriculture there in 1864 He was closely and influentially identified with the movement for agricultural education and research in the United States for more than half a century With Claenae King, he surveyed large tracts of the Sierras, one of the highest peaks in those mountains being named in his honor In 1904 he was one of the party on the trip of the *Muanda* into Arctic regions, and in 1906 was a member of the United States Forestry Commission He contributed to the *Report on Cereal Production in the United States* tenth census (1883), and wrote *Botany of California* (1875)

BREWERS' GRAINS The residue resulting in the manufacture of beer from grain, usually barley, much used as a feed for live stock In beer making the grain is treated with malt to change the starch into sugar, which is then fermented, yielding alcohol The residue of the grain, which constitutes the brewers' grains, is very wet, containing some 75 per cent of water It is sometimes sold in this wet condition, for immediate use in the vicinity of the brewery, but spoils rapidly On account of this and the putrid odor it causes in stables, its use for milch cows is often objected to There is nothing in itself, wet brewers' grains which is poisonous or deleterious to milk production, provided they are fed in tight mangers which are kept clean The partially spoiled grains should not be used for feeding Brewers' grains are often dried by artificial heat, freeing them very largely of their water, in which condition they keep indefinitely The average composition of the dried grains is as follows water 7.8, ash 3.5, protein 22.6, fibre 12.3, nitrogen-free extract 46.8, and fat 6.5 per cent They are an excellent feeding stuff, especially for cattle and horses, ranking with wheat bran and oil meals in palatability and general effects

BREWERTON, HENRY (1801-79) An American soldier, born in New York City He graduated in 1819 at the United States Military Academy, was commissioned in the corps of

engineers, and rose in that service to the rank of colonel (1864) and brevet brigadier general (1865). From 1845 to 1852 he was superintendent of the United States Military Academy, from 1861 to 1864 directed the improvements in Baltimore harbor and at the mouth of the Susquehanna River, and during the Civil War was superintending engineer of the fortifications of Baltimore harbor and the defenses of Delaware Bay and River. He was among those who contributed to the early extension of the system of coast and frontier defenses.

BREWING (AS. *brēwan*, OHG. *brīuan*, Ger. *brauen*, Icel. *brugga*, to brew; cf. Gk. *spīron*, *bryton*, a kind of beer or cider). The process of making beer, ale, or other fermented beverages which do not undergo distillation. This art, which is one of the oldest (see BEER), has been improved from time to time so that at the present day, by the aid of chemistry and bacteriology, the manufacture of beer involves a high degree of technical skill. While it is usual to speak of the manufacture of beer as brewing and the place where it is made as a brewery, yet, to be more exact, there are two distinct and separate processes to be considered, the malting and brewing proper.

The raw materials for making beer are water, barley, and hops. The first process in the manufacture is the malting of the barley.

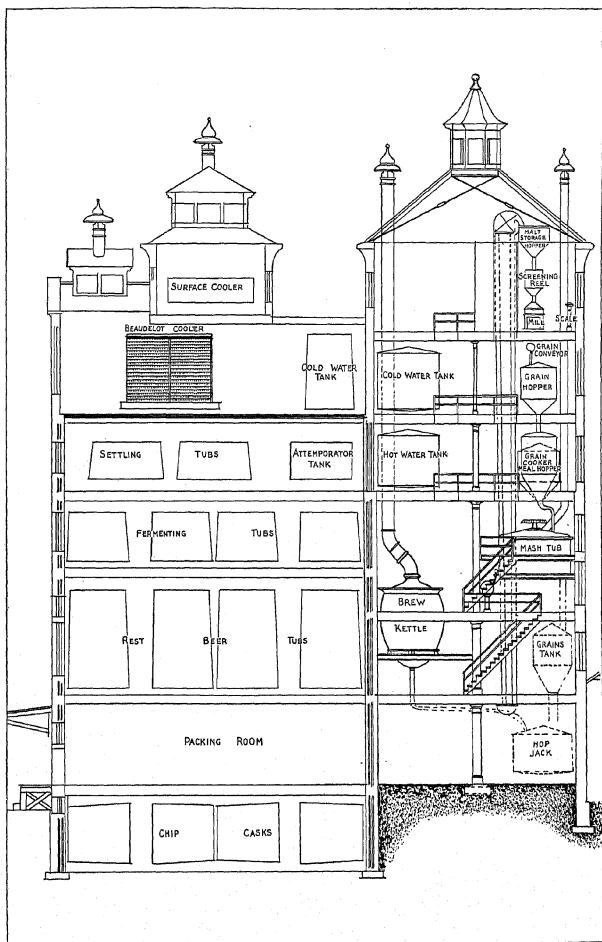

Malting. The grain is first steeped by placing it in wooden, cement, or metal cisterns and covering it with cold water. This process of steeping lasts from 45 to 72 hours, the water being drained off about once a day and replaced by fresh water. During the process of steeping the barley absorbs a portion of the water, which causes it to swell and soften. After being finally drained, the barley is taken from the steeping tanks and spread to a depth of one foot on the malt-house germinating floor. This part of the process is known as "couching." In this position the grain begins to germinate or grow sprouts, which, if allowed to develop, would form the future rootlets and blades of the barley. This process is one which the maltster watches with the utmost care, since upon its being properly accomplished depends much of the final success of the brew. The chief requisites to be observed are that the germination shall be slow and regular, that it shall not proceed at too high a temperature, and that it shall be checked at the proper time. Different varieties of barley germinate with different speeds, and the maltster has to study the peculiarities of each variety and regulate his work accordingly. This regulation is accomplished by thinning out the couches; by regularly turning the grain over and respreading it; by letting in or shutting out the warmer or the colder outside air, and by resprinkling the grain with water. The thinning down of the couches is technically known as "flooring." The duration of the process of germination varies, but it usually is over six days. The next step is to check the germination, and this is done by kiln drying. The kiln consists of a building with two or three perforated floors. The upper floors are usually provided with dumping devices for the purpose of allowing an easy transfer of the grain to the floor below. The kiln house is supplied with furnaces whose purpose it is to furnish heat, and in which anthracite pea coal or coke is burned. In drying, the grain, or green malt as it is called, is spread on the upper floor and when

much of the water has been expelled it is dumped to the floor below where the temperature is higher. The final drying temperature for pale malt, used for making beer of the Pilsen type, is around 145° F., and in the neighborhood of 220° F. for dark malt, used for Munich type beers. In addition to checking germination, kilning produces certain substances which impart an aromatic flavor to the beer.

Brewing. The first operation in brewing is to crush, or technically to "bruse," the malted grain by passing it between iron rollers, the ground product from which is termed "grist." The grist is then mixed mechanically with warm water until it has about the consistency of ordinary porridge in the mash tubs, where the temperature is raised to about 165° F. within a certain period of time. Modern mash tubs are provided with mechanical mixers for agitating the mixed grist and water which is now called the "mash." If raw grain is to be used, it is introduced at this stage. Before adding it to the mash, however, it must undergo a process of preliminary solution. This is accomplished by boiling the grain for a time (in water) in ordinary or pressure tanks, called cookers, then cooling the mixture down to about 160° F. and adding some malted barley. After standing for one-quarter of an hour or so the temperature is raised to about 190° F., and the partly soluble raw-grain mash is run into the mash tub containing the all-malt mash. Here saccharification takes place. If prepared cereals, such as corn flakes, are used, the preliminary dissolution treatment is unnecessary, because these materials are worked up with the malt in one mash tub. After standing in the mash tub from 30 to 45 minutes, the liquor is drained off from the bottom, hot water being slowly and evenly run over the top of the residus thoroughly to wash or purge the grist from the liquor, which is now called "wort." The wort is allowed to stand for a brief time to clarify and is then drawn off into copper boilers, where it is boiled with hops. From one to three bushels of malt and from one to three pounds of hops are used for a 31-gallon (U. S.) barrel of all-malt beer. After being boiled down to the proper concentration in the copper kettles, the wort is drawn off and cooled quickly by passing it through or over pipes (Baudelot cooler) in which cold water and ammonia circulate (different pipes). In the older types of breweries the surface cooler (cool ship) is still used. This consists of a large shallow vessel which allows a large surface of wort to be exposed to the air at one time; this causes rapid cooling. From the cooler the wort is run into the vats where fermentation takes place. (See FERMENTATION.) Fermentation is started by adding about five pounds of good yeast to 100 gallons of wort, the yeast used always being some which has been reserved from a previous brewing of the same kind of beer. Fermentation is allowed to progress for a number of days, and the time depends very much upon the kind of beer brewed. Top fermentation beers require but a few days, while bottom fermentation beers need 8 to 16 days. It is comparatively slow at first and then rapidly increases as the wort begins to "work" and the temperature has risen considerably; large quantities of carbonic-acid gas are thrown off, and the surface of the wort is covered with a thick layer of scum. The next process is to run the fermented liquor into other vats, known as

*

BREWING

CROSS SECTION OF A MODERN BREWERY

*

cleansing or settling vats, which, like some fermentation vats, are usually provided with some means for cooling their contents, where a mild secondary fermentation occurs, which throws off the remnants of the yeast in the shape of scum. The beer is then drawn off into casks, where it is stored, for a greater or less length of time and under different conditions of temperature, to mature. The time required and conditions provided for maturing several of the more common varieties of beer are different in their precise natures and are discussed under BEER. Before marketing many of the beers are fined, chilled, filtered, charged with carbonic-acid gas and pasteurized. This increases the keeping qualities and improves the appearance.

Technology and Chemistry. The two preceding paragraphs outline briefly the processes of malting and brewing. Briefly enumerated, the technical considerations which call for the most particular attention are (1) the nature and quality of the grain used, (2) the malting of the grain, (3) the temperature at the commencement of mashing and again at the beginning of fermentation, and (4) the quality of the water used. Regarding the choice of barleys for brewing, they should be thoroughly ripened and should be carefully harvested and handled to preserve the skin or husk of the kernel, since when the kernel is bruised or has its skin broken, mold, bacteria, and wild yeasts are likely to attack it and cause trouble, if not disaster, in malting and brewing. Regarding the incipient temperature of the mash and of the wort at the commencement of fermentation, it can only be said here that it is held to be of prime importance, and if not accurately controlled may result in spoiling the brew. In respect to the water used, the principal requirements are that it should be absolutely pure and should be somewhat "hard," i.e., it should contain lime salts, especially in the form of gypsum. The principal chemical actions occur during malting, when the mash is being made, and during fermentation. During the malting or sprouting of the grain substances known as enzymes are produced. One of these is known as diastase or amylase and has the property of changing starch into dextrin and maltose. This process is known technically as saccharification and is one of the most important which enter in the brewing of beer. Another enzyme formed in barley during the malting process is peptase, it has the property of converting the insoluble proteins into peptones and other substances soluble in water.

During fermentation the sugars (maltose, etc.) and some of the dextrins are decomposed by the enzymes (maltase, zymase, etc.) contained in yeast, into alcohol and carbonic-acid gas. It has been found by experiment, and verified in practice, that 100 parts of sugar when fermented will yield about 50 parts of alcohol and 47 parts of carbonic-acid gas. Other products formed are succinic acid, glycerine, etc.

The amount of alcohol in beer is controlled almost entirely by the temperatures employed in making the wort. High temperatures tend to yield beers with a low alcohol percentage, and this fact is taken advantage of in the preparation of the so-called temperance beers. See ADULTERATION.

BREWSTER, BENJAMIN HARRIS (1816-88). A notable American lawyer. He was born in New Jersey, graduated at Princeton in 1834, and was admitted to the bar of Philadelphia in 1838. In 1846 he was one of the commissioners who decided the claims of the Cherokee Indians against the United States. He was appointed Attorney-General of Pennsylvania in 1867, and during his term of office succeeded in breaking up the notorious "Gettysburg Lottery" scheme. From 1881 to 1885 he was Attorney-General of the United States, in President Arthur's cabinet, and in this capacity conducted the "Star Route" trials with great energy and ability.

BREWSTER, CHAUNCEY BUNCE (1848-) An American Protestant Episcopal bishop. He was born at Windham, Conn., and was educated at Yale University. After occupying rectories at Rye, N. Y. (1873-81), Detroit (1881-85), Baltimore (1885-88), and Brooklyn (1888-97), he was in 1899 elected Bishop of Connecticut. The following are his principal publications: *The Key of Life*, a series of Good Friday addresses (1894), *Aspects of Revelation* (1901), *The Catholic Ideal of the Church* (1905), *The Kingdom of God and American Life* (1912).

BREWSTER, SIR DAVID (1781-1868). An eminent Scotch physicist, born at Jedburgh. He was educated for the Church of Scotland at the University of Edinburgh and was licensed to preach by the presbytery of Edinburgh. Instead of following the life of a clergyman, he devoted himself to scientific study and research and literature, and in 1808 he became the editor of the *Edinburgh Encyclopædia*, to which he contributed many important scientific articles. Previous to this he had entered deeply on the study of optics, with which his name is now enduringly associated. The optical toy called the kaleidoscope was invented by him in 1816, and he published a treatise on the instrument three years later. The stereoscope is also largely his invention, the honor being shared with Wheatstone, though the divided lenses and their arrangement are due entirely to Brewster. In 1817, in conjunction with Professor Jameson, he edited the *Edinburgh Philosophical Journal*, the name of which, in 1819, was changed to the *Edinburgh Journal of Science*, and in 1831 he was one of the founders of the British Association for the Advancement of Science. Brewster's scientific work brought to him many honors. In 1815 he obtained the Copley medal of the Royal Society for one of his optical discoveries and soon after was elected a fellow. In 1816 he received half of the physical prize bestowed by the French Institute for two of the most important scientific discoveries made in Europe during the two preceding years. In 1819 the Royal Society awarded him the Rumford gold and silver medals for his discovery connected with the polarization of light. In 1825 he became corresponding member of the Institute of France. In 1831 he was knighted and had a

pension conferred upon him. In 1838 he was chosen principal of the united colleges of St. Leonard and St. Salvador, St. Andrews. In 1849, on the death of Berzelius in the preceding year, he was elected one of the eight foreign associates of the French Institute, the highest scientific distinction in Europe. Brewster was also a member of the Imperial and Royal Academies of St. Petersburg, Berlin, Copenhagen, and Stockholm, and a foreign associate of the National Academy of Sciences of the United States. He presided over the British Association and in 1851 over the Peace Congress held in London. In 1859 he was chosen vice chancellor of the University of Edinburgh. His principal work is his *Life of Newton*, first published in 1828 and issued in a totally new and greatly enlarged form in 1855. Among his other works are his interesting *Letters on Natural Magic*, addressed to Sir Walter Scott; *More Worlds than One* (1854); his treatises on the kaleidoscope and on optics (*Cabinet Cyclopædia*); his *Martyrs of Science*; and his treatises in the *Encyclopædia Britannica* on electricity, magnetism, optics, the stereoscope, etc. Among the periodicals to which he contributed largely are the *Edinburgh and North British reviews*. Consult Gordon, *Home Life of Brewster* (Edinburgh, 1869).

BREWSTER, FREDERICK CARROLL (1825-98). An American lawyer, born in Philadelphia, Pa. He graduated at the University of Pennsylvania, was admitted to the bar in 1844, and from 1862 to 1866 was city solicitor of Philadelphia. In the latter year he became judge of the Court of Common Pleas, and in 1869 Attorney-General of Pennsylvania. He was instrumental in obtaining for the city of Philadelphia the Stephen Girard bequest and the Schuylkill River Bridge. His publications include a *Digest of Pennsylvania Cases* (1869); *Brewster's Reports* (4 vols., 1869-73); *Practice in Pennsylvania Courts* (1888).

BREWSTER, WILLIAM (c1560-1644). A leader of the "Pilgrims," generally known as Elder Brewster, who came to America in the *Mayflower* in 1620. He was born at Scrooby, Nottinghamshire, studied for a time at Cambridge, and from 1584 to 1587 was in the service of William Davison, then Ambassador to the Low Countries (and afterward the Assistant Secretary of State of Queen Elizabeth), who, says Bradford, regarded him as "so discreet and faithful that he trusted him above all others who were with him." About 1587 Brewster retired to Scrooby, "to live in the country in good esteem amongst his friends and the good gentlemen of those parts, especially the godly and religious." Here he occupied the old Scrooby manor house, and for some years held the position of "post," which was then frequently filled by men of high social standing, and which involved the entertainment of travelers, as well as the dispatch of the mails and the supplying of relays of horses. He was in thorough sympathy with the Separatists at Scrooby, who on each Sunday assembled for worship at the manor house. In 1608 he was one of the company of Nonconformists who, to avoid persecution, removed to Holland; and at Leyden, his fortune having been exhausted, he supported himself by teaching English to the students at the university, and by publishing books whose circulation was prohibited by the English government. With Bradford, Carver, and Winslow, he urged the migration to America, and with

Bradford he went to England in 1619 and secured a patent from the Virginia Company for a tract of land in America. In the following year he crossed the Atlantic, with the first company of "Pilgrims," and for the next 24 years was one of the leaders at Plymouth, where he did much by his energy and cheerful optimism to make the colonizing experiment a success. Having been the ruling elder of the congregation in Scrooby, Amsterdam, and Leyden, he continued to act as such at Plymouth, and until 1620 was also a teacher and preacher, holding services twice each Lord's Day, though he always refused to administer the sacrament. At his death he left a library of more than 300 volumes, a catalogue of which has been preserved. Bradford prepared an interesting *Memoir of Elder Brewster*, which may be found in Young's *Chronicles of the Pilgrims* (Boston, 1841), and in vol. iii, 5th series, of the *Collections of the Massachusetts Historical Society*. Consult Steele, *Chief of the Pilgrims; or the Life and Times of William Brewster* (Philadelphia, 1857).

BREWSTER, WILLIAM (1851-). An American ornithologist, born at Wakefield, Mass. He graduated from the Cambridge High School. From 1880 to 1887 he had charge of the collection of birds and mammals of the Boston Society of Natural History, from 1885 to 1900 he was in charge of the department of mammals and birds, and after the latter year of birds alone, at the Cambridge Museum of Comparative Zoölogy. He devoted most of his time to managing his private museum of ornithology. His publications include: *Bird Migration* (1886); *The Birds of the Cape Region of Lower California* (1902); *The Birds of the Cambridge Region of Massachusetts* (1906).

BREWSTER'S LAW. See LIGHT, Polarization.

BREWTON, brū'tŭn. A city and the county seat of Escambia Co., Ala., 105 miles south by west of the State capital, Montgomery, on the Louisville and Nashville Railroad (Map: Alabama, B 4). The city contains an industrial school for girls and the Brewton Collegiate Institute. It has truck-farming interests and various manufactures of wooden products. Pop., 1900, 1882; 1910, 2185.

BREYMANN, brīm'ān, HERMANN (1843-1910). A German philologist. He was born at Oker, near Harzburg, and studied philology at the universities of Göttingen, Bonn, Marburg, and Paris. From 1867 to 1875 he lived in Manchester and London. In 1875 he was appointed professor of French and English at the University of Munich. He was one of the foremost authorities on pedagogical questions affecting instruction in modern languages. In addition to the *Münchener Beiträge zur romanischen und englischen Philologie*, of which he was the editor (1890 ff.), Breymann published the following important works: *Les deux livres des Machabées* (1868); *Marlowe's Dr. Faustus* (1889); *Bearing of the Study of Modern Languages on Education at Large* (1872); *Die, sein Leben, seine Werke* (1878); *On Provençal Literature* (1875); *Die neusprachliche Reform-Literatur 1876-93* (1895); *1894-99* (1900); *Calderon Studien* (1905); *Die phonetische Literatur von 1876-95* (Leipzig, 1897).

BRIALMONT, bré'al'mŏn', HENRI ALEXIS (1821-1903). A Belgian engineer and military writer. He published a large number of works

on the art and methods of military fortification and is regarded as an authority on this subject. He designed the principal fortifications of Antwerp, the fortifications of Bucharest (1883), and those of Liège and Namur, in 1887. Among his publications are *Precis d'art militaire* (4 vols, 1850), *La fortification du temps présent* (2 vols, 1885), *Progres de la défense des états et de la fortification permanente depuis Tanbon* (1898).

BRI'AN BOROMHEE, bo-rom', or BORU, bo-rōw' (926-1014). A famous King of Ireland. He became King of Cashel, comprising the present counties of Tipperary and Clare, in 978. In 1001, after defeating Maelsechlainn, he was acknowledged the chief King of Ireland. The surname Boromhe, signifying 'tax,' was given him in consequence of the tribute in kind he levied from the various provinces. He lived in the Dun of Cenn Coradh, in a state of rude plenty. He is said to have defeated the Danes in 25 pitched battles. In the battle of Clontarf, April 23, 1014, in which he was killed, Brian gained a signal victory over a united army of revolted natives and Danes, the power of the latter receiving a shock from which it never recovered. Brian Boru is the great hero of the Irish, but fact and fiction have become so mingled in the accounts of his life that it is difficult to form an accurate picture of the real warrior chieftain.

BRIANCHON, bi'ān'shōn', CHARLES JULIEN (1785-1864). A French mathematician, born in Sévres. He studied at the Ecole Polytechnique, in 1808 was appointed lieutenant of artillery, in 1815 assistant director of the manufacture of arms, and in 1818 a professor at the Ecole d'Artillerie. His publications include *Application de la théorie des transversales* (1818) and *Essai chimique sur les réactions foudroyantes* (1825). He is best known for a theorem which appeared in 1808 in the *Journal de l'Ecole Polytechnique*, in an article later expanded into *Mémoires sur les lignes du second ordre* (1817). One form of the statement of the theorem is: The three diagonals of every hexagon circumscribed to a conic meet in a point. See GEOMETRY.

BRIANÇON, bi'ān'sōn' (anciently, Lat *Brigantium*, the town on the heights, from Celt *bragh*, *brig*, heap, pile, elevation). A strongly fortified town in the department of the Hautes-Alpes, France, situated at the confluence of the Durance and Guisane, about 35 miles northeast of Gap (Map France, S, L 4). It is the highest town in France, being more than 4300 feet above sea level. It is a fortress of the first class, commands the entrance into Italy by Mont Genevre and the principal passes, and is the principal military depot and arsenal in the French Alps. Briançon has manufactures of silk, cotton, hosiery, and cutlery. Pop., 1901, 7426, 1911, 7888. In Roman times the town was called Brigantium and lay on the direct route from Italy to Embrun and Gap. It was not fortified by the French until 1722, and the building of its 10 forts has gone on from that date until today.

BRIAND, bi'ānd', ARISTIDE (1803-) A French statesman born at Nantes. Although he was trained as a lawyer, M. Briand's interests have always been in the fields of journalism and politics. For several years he was a contributor to Radical and Socialist journals like *La Lanterne*, *Petite République*, and *L'Humanité*. He entered politics as an advanced Radical—ad-

vanced even to the point of Socialism—and made himself conspicuous by advocating the general strike. In 1902 he was elected to the Chamber of Deputies as a Socialist Radical. M. Briand soon attracted attention in Parliament by his brilliant exposition of difficult and involved subjects. His talents won him the position of reporter or chairman of the committee to draft the bill separating church and state. The report of this committee, drawn up mainly by M. Briand himself, is a masterpiece of historic study, keen analysis, and constructive suggestion, and became the basis for the law of separation. In 1906 he became Minister of Public Instruction and Worship in the Sarrien cabinet and applied the law with great sagacity and tact, for although an anticlerical, M. Briand is not an extremist, and for that reason he won the hearty support of all moderate people in France.

In 1909 M. Briand became Prime Minister. As he advanced in power, his views became more and more conservative, and he was expelled from the Socialist party. The great event of his ministry was the railroad strike of 1910. The General Confederation of Labor, a revolutionary Syndicalist organization, called a general strike on all French railroads, and over 30,000 men responded. France was completely at the mercy of the strikers, and acts of violence or *sabotage* became frequent. Prime Minister Briand, seeing the revolutionary character of the movement, decided upon an unusual but effective course. The strikers were "called to the colors" as reserves for three weeks' military training. They were assigned to protect the railroads. In other words, they became their own strike breakers. This move succeeded, and the strike immediately collapsed, although it earned for M. Briand the hatred of the French working class, who bitterly denounced him as a renegade and a dictator. His defense was that the government was confronted by what was virtually rebellion, that society had the right to use all means, even illegal ones, for its own safety on the ground of *salus publica suprema lex*. On Feb. 27, 1911, the Briand Ministry fell because it was charged with having shown remissness in enforcing the church laws. Briand again became Prime Minister in 1913, but his tenure of office was very short. The bill establishing proportional representation supported by the cabinet passed the Chamber, but was defeated in the Senate. M. Briand then resigned. Soon thereafter Briand and Louis Barthou, also a former Premier, together with many Republican Senators and Deputies, formed a new political organization, the "Briandist party," which should labor for the welfare of France as a whole, not for the satisfaction of local constituencies.

BRIANSKY, biyānsk, or **BRYANSKY** (RUSS., earlier *Debnyansk*, Slav *Dibryansk*, from *dobry*, thick, forest, for which the neighborhood was quite famous). A district town in the government of Orel, Russia, on the right bank of the navigable Desna, about 80 miles northwest of Orel (Map Russia, D 4). It is divided into several parts by a number of short streams and contains a large number of churches, among which the Pokrov Cathedral is the most prominent. In the vicinity of the town is situated the monastery of Svensk-Uspensk, dating from the thirteenth century and containing a theological seminary. The settlement around the monastery is the place of an important annual fair.

Briansk has a considerable trade in hemp, leather, tumber, ropes, grain, and salt. The chief manufacturing establishments are iron foundries, tanneries, and glass works. There is also an important arsenal. Pop., 1888, 20,200; 1897, 23,520.

BRIAREUS, bri-ä-ré-üs (Gk. *Briareus*, *Briareüs*), or *Ægeon*. One of the three sons of Uranus and Gæa. Homer (*Iliad*, i. 403) declares that men called him *Ægeon*, the gods Briareus. The other sons were Cottus and Gyges, or Gyges, and each of the three had 100 arms and 50 heads. They assisted Zeus when the Titans made war against Olympus; they were set by Zeus to guard the defeated Titans in Tartarus. In Homer Briareus appears alone as a friend of Thetis, and ally of Zeus during a revolt of the gods. In some accounts he is represented as dwelling in the depths of the *Ægean Sea*.

BRIBERY, bri-br'ë-r-i (OF. *brüberie*, from OF. *bride*, bit of bread given to a beggar, from Breton *brad*, to break). The offering, promising, giving, or receiving of money, goods, employment, or personal advantage of any kind with a view to unlawfully influence the receiver in the exercise of a public duty. Such public duties are those of judges, legislators, executive officers of government or state, voters in the exercise of suffrage, customs officers, and others. The person giving, as well as the one receiving, the bribe is guilty of the crime of bribery. The United States and the several States in their statutes define the offense and impose severe penalties of fine or imprisonment, or both, for conviction of bribery.

Judicial bribery is defined by Greenleaf as the "receiving or offering any undue reward by or to any person whose ordinary profession or business relates to the administration of public justice, in order to influence his behavior in office and incline him to act contrary to the rules of honesty and integrity." It is a matter of congratulation that the higher courts of the United States have been almost uniformly free from the taint of suspicion of bribery. The United States Supreme Court has a spotless record in this respect, as have most of the higher courts of the several States. The offense has been rare, also, in the history of the administration of justice in England. It was punishable at common law. Perhaps the earliest reported case of judicial bribery is that of Sir William Thorpe in 1351. This was followed by the impeachment of Chancellor Michael de la Pole in 1384. But the most celebrated case of judicial bribery in England is that of Lord Bacon, who pleaded guilty to corruption in office, and who was sentenced to pay a fine of £40,000 and to imprisonment during the King's pleasure, incapacity for office, and exclusion from Parliament.

The corruption of other public officials was also a common-law offense, whether the bribery was employed to induce the officer to act or to refrain from acting in his official capacity. The mere offer of a bribe, though it was refused, constituted a common-law misdemeanor. The bribery of jurors is considered under *EMBRACERY*.

The form of bribery which is most dangerous at present, as well as the one which has called forth the greatest amount of legislation, is that which aims at the corruption of voters at public elections. Modern statutes upon this subject are dealt with under *ELECTORAL REFORM* and *CORRUPT PRACTICES*. An announcement by a candidate for office that, if elected, he will serve

at a less salary than that provided by law has been held to be an offer of a bribe to the voters. (See *ELECTION*; *ELECTORAL REFORM*; *CORRUPT PRACTICES*; *CRIMINAL LAW*.) In England and several of the United States the bribery of representatives of labor organizations, as well as of a private agent, employee, or servant, has been made a criminal offense.

BRIC-A-BRAC (Fr. possibly from OF. *de bris et de broc*, by hook or by crook, or it may be a reduplication with a change of vowel, like *rick-rack*, *niff-raff*, etc.). A word of uncertain origin denoting objects of many kinds used for decorative purposes, such as old furniture, *objets de vertu*, or ornaments, interesting because of rarity, or merely because they are quaint or obsolete. The term usually designates small objects and differs from *curio* in that its connotation extends only to articles that have some claim to æsthetic merit. Bric-a-brac is often of archaeological and even of ethnological interest, but the taste sometimes degenerates into a "fad" and often results in overloading spaces in dwellings. When systematic or historic collections are made on a large scale, they may be extremely useful as preserving for future generations the minor notes of many of the fast-vanishing modes of life, manners, and practices of the past revived through their study.

BRICE, CALVIN STEWART (1845-98). An American lawyer and politician. He was born in Ohio and served in the Union army from 1862 to 1865. He graduated at Miami University in 1863, practiced law for a short time, but soon turned his attention to railroad affairs, and was identified with the East Tennessee, the Richmond Terminal, the Duluth, South Shore, and Atlantic, and several other roads. At the time of his death he was interested in the American China Development Company. After having served as chairman of the Democratic National Campaign Committee in 1889, he was a member of the United States Senate from 1890 to 1897.

BRICK (probably allied to *break*, originally meaning a fragment; cf. Fr. *brigue*, a piece, fragment). The earliest examples of this branch of the ceramic art were doubtless the sun-dried bricks of Egypt, Assyria, and Babylonia. In America bricks were made in Virginia as early as 1611; in Massachusetts in 1620, and in Phila-

TEMPERING DEVICE AND AUGER OF BRICK MACHINE.

delphia in 1633. All bricks used prior to that date were probably imported. The hand-power brick machines were patented as early as 1800, and a steam-power press was invented by Adams of Philadelphia not later than 1840.

Raw Materials Used. *Common bricks* are

made from clays or shales, usually of low grade, and mostly of red-burning character, although in some districts cream-burning ones only are available. They are required to mold readily and burn hard at a moderate temperature. *Face*

SIDE-CUTTING MACHINE

brick are made from red-burning clays or shales, buff-burning clays of either refractory or calcareous character, or more rarely white-burning clays. The materials are usually exposed to higher temperatures in burning than the common-brick clays. *Fire brick* are manufactured from a clay of refractory character.

Whatever the kind of brick to be made, it is seldom molded from one clay alone, a mixture of clays being used, or else a mixture of clay and sand, in order to secure a material of the proper plasticity, shrinkage, etc.

Kinds of Brick. The following names, representative of different shapes and qualities, are now widely recognized. *Air brick*, hollow or pierced brick built into wall to allow passage of air, *Arch brick*, a term applied to either wedge-shaped brick, used for the voussoir of an arch, or to brick taken from the arches of a kiln. The latter type are hard-burned and sometimes even rough and twisted by excessive heating, *Ashlar brick*, a term often applied to certain brick, whose one edge is rough chiseled to resemble rock-faced stone, *Common brick*, any brick used for ordinary structural work, where appearance is of minor importance, *Fire brick*, one that stands a high degree of heat, *Flashed brick*, those face brick whose surface has been darkened by special treatment during firing, *Hollow brick*, those molded with hollow spaces and used for partitions, *Norman tile*, brick having the dimensions $12 \times 2\frac{1}{4} \times 4$ inches, *Ornamental brick*, those whose surface is ornamented with a relief design, *Pale brick*, underburned brick, *Paving brick*, those of low absorption and good abrasive resistance, suitable for paving purposes, *Pompeian brick*, of same size as Roman tile, but having a brown body

with iron spots and flashed edge, *Pressed brick*, a loose term, applied to any smooth-faced and sharp-edged brick, *Roman tile*, a brick $12 \times 1\frac{1}{2} \times 4$ inches, *Rough-textured brick*, a style now much used, made by the stiff mud process and having a roughened surface. They are known under patented names, such as Tapestry, Hightex, Devonshire, etc., *Salmon brick*, imperfectly burned ones, *Sewer brick*, a general term applied to common brick burned hard enough to be practically nonabsorbent and, therefore, adapted for use as sewer linings.

Brick Manufacture. All bricks go through the same stages in the process of manufacture, viz, preparation, molding, drying, and burning. If the clay or shale is very hard, it needs a preliminary crushing before it is mixed to a plastic mass with water, as is necessary for all processes of molding except the dry-press method. This mixing or *tempering*, as it is called, is done in different types of machines, such as a ring pit, pug mill, or wet pan.

Molding was formerly done by hand, and this method is still followed at small yards, or for the manufacture of special shapes, and certain kinds of fire brick, but machine molding is becoming more and more common. Molding machines are of the soft-mud, stiff-mud, or wire-cut, and dry-press types. Soft-mud machines consist of an upright receptacle of wood or iron, containing a knife-bearing, revolving central shaft, with curved arms at the bottom to force the clay into the press box. The molds are sanded, then fed in automatically beneath the press box. After the molds are filled under pressure, they are moved forward to the delivery table. The bricks made by this process show five sanded surfaces, a sixth rough one, and possess a homogeneous structure. Stiff mud

STEAM-POWER SOFT-MUD BRICK MACHINE

machines treat a stiffly tempered clay, which is forced through a rectangular die by an auger, which sends out a continuous bar of the material. This bar is cut up into bricks, either by parallel wires set on a frame or else by means

of a revolving automatic cutter. Stiff-mud bricks have four smooth surfaces, and two rough ones produced by the cutting actions of the wires. They sometimes show an objectionable laminated structure, which is specially pronounced when very plastic clays are used.

Dry-press machines use a pulverized, screened clay, which is fed from a hopper through canvas tubes or chargers, into the molds, where they are subjected to strong pressure. Dry-press bricks have smooth surfaces and sharp corners and edges. They often show a granulated texture, and unless hard burned are liable to be more porous than brick molded by the other processes.

Soft-mud and stiff-mud brick have to be dried before they are burned. This may be done in the open air, under covered sheds, or in tunnels warmed by artificial heat. Burning is done in kilns (q.v.) and the temperature reached depends on the clay and hardness of product required. Common brick are rarely fired above 1050° C., while face brick may reach a temperature of 1200° or 1300° C.

Testing of Brick. Structural brick should be tested for crushing strength, transverse strength, absorption, frost, and fire resistance. Paving brick are tested for crushing strength, frost, and abrasive resistance. Fire brick must be tested for absorption, refractoriness, and resistance to load when heated to a high temperature. Enameled brick should be specially tested with reference to opacity and smoothness of enamel, and its freedom from tendency to craze.

Archæology of Brick. Throughout antiquity two kinds of brick were used, the crude or sun-dried and the kiln-dried or fired bricks. Brickmaking was invented in Babylonia, where nature had provided no other building material, there being no quarries or forests; and if, as is asserted by eminent authorities, the earliest civilization was formed in Babylonia, bricks may be deemed the earliest material used in permanent construction, as well as the basis for the invention of the arch, dome, tunnel, and other methods of vaulting. Buildings made of bricks have been discovered dating long before 4000 B.C. The same processes were followed in Egypt, where, however, the use of brick was not nearly so general, as stone quarries were abundant. Assyria followed Babylonia far more closely, using stone hardly at all, except occasionally for foundations and facings. In the preparation of crude bricks, the clay, mixed with finely chopped straw with a fixed proportion of water and thoroughly kneaded, was shaped in molds varying in size from 14 to 16½ inches square and from 2 to 4 inches thick. The Babylonians allowed the bricks to dry thoroughly before use, but the Assyrians were satisfied with brief and imperfect desiccation; for usually it is possible to detect separate courses and even separate bricks in Babylonian ruins, but in the Assyrian walls all

individuality has been lost through the adhesion of moist surfaces.

The kiln-dried bricks were used in much smaller quantities, for facing the masses of crude brick so as to preserve them from disintegration, especially by water, and for thin and inner walls. These bricks were burned by wood fires in ovens or flare kilns. They also were commonly square, somewhat smaller than the crude brick, about a foot in length and breadth. Usually one of their flat sides was stamped with the names and titles of the reigning king, and this side was laid downward. These bricks have been the best means of fixing the dates of many temples and palaces in Babylonia and Assyria. Besides the regular-sized burned bricks, others were molded in special shapes and sizes; segments of circles for use in columns; wedge-shaped, for use in arches; triangular, for corners, even convex. Undoubtedly the Babylonians deserve the palm for both quality and variety. The bricks were laid in liquid clay, lime mortar, or bitumen. According to Herodotus, in building the walls of Babylon the clay from the trenches was used for making the bricks, which were then laid in "hot asphalt for cement, and between every thirtieth course of bricks placing mats of woven reeds." (Cf. Gen. xi. 3, for the building of the Tower of Babel.) A third form of brick used by Babylonians and Assyrians was the enameled brick, in which the body of the brick was only lightly fired so that the enamel could better penetrate.

We do not associate bricks with the Greeks, yet it is certain that among them crude bricks were in general use, especially in the earliest times. At Troy, Tyrins, and other cities of the Mycenaean age, such bricks formed the constructive material of houses and palaces, together with wood. In fact, this seems to have been the case with the Hittites and other early Mediterranean peoples. For this reason only the stone foundations remain of most structures, as crude bricks, when used for thin walls, cannot last. When in historic times the Greeks had in general substituted stone for wood, crude brick, and terra cotta in their public buildings, they still often used crude brick for city walls, because, as Pausanias says, it is "safer against the shock of military engines than either burnt brick or stone." There were two sizes: 14½ inches square for public buildings; 11½ inches square for private buildings; and half bricks, to be used in alternate courses. Burned bricks appear hardly to have been used at all by the Greeks until after the Roman conquest. The Greeks called crude bricks *plinthoi omai*, and fired bricks *plinthoi optai*; the Roman names were *lateres crudi* and *lateres cocti* or *coctiles*.

The Romans began by using crude bricks almost exclusively. Vitruvius, Pliny, Columella, Varro, and other Latin authors give interesting details as to their manufacture. An especially choice kind was made in parts of Spain and Asia Minor, so light that they would float in water. They also resisted dampness. It was considered advisable to let bricks dry for two years before use, but the laws of Utica required five years. The best period for manufacture was said to be May, because summer bricks dry so quickly on the surface that they retain an internal dampness which causes cracks. The Roman brick was smaller than any hitherto made, and the square form was for the first time abandoned. The norm was 12 × 6 inches. Triangular bricks

were also used for facing walls of rough concrete. When the Empire began, under Augustus, the Romans had largely substituted fired for crude brick in both private and public buildings, and the adoption of concrete for heavy walls, faced with fired bricks, in place of the earlier stone walls, gave permanent prominence to this kind of brick in construction throughout the civilized world. The modern Italian bricks have preserved many qualities of the old Roman ones, which were substantially tiles, beaten flat and dried on the ground, then stacked edgewise in the furnaces on crosspieces or on the floor itself. Roman-brick furnaces have been found on sites in Italy, Gaul, Germany, England, etc. In laying them the mortar bed was prepared first, and the brick laid with both hands. The Romans not only brought back the Babylonian popularity of brick, but also revived Babylonian methods. They added an inscription to their molds, bearing the name of the reigning emperor, magistrate, contractor, or manufacturer, of great value in identifying and dating buildings. They also used a variety of shapes to suit all purposes and constructive forms. Such bricks verge on terra cotta (qv), under which head the combination of plastic earthenware with brickwork will be described. A geographical survey will show that brick did not become equally popular in all parts of the Roman Empire. For instance, in Syria, in north Africa, in the south of France, and in Asia Minor, the Greek tradition of stone construction was maintained nearly intact. When Christian architecture arose, the solid Roman concrete construction was abandoned, and brickwork became even more prevalent, though stone was still used in the regions just named, except that brick, being adopted at once by Byzantine architecture, drove stone out of most Hellenic lands by the seventh century. But the universal decadence affected even brickmaking. All the basilical churches being of brick (except in Syria, etc.), it is easy to compare their quality in different centuries. Often the bricks were drowed in mortar, especially in Gaul. Really good brickwork does not return until the twelfth century in the West. But meanwhile the good traditions had been maintained in the East, not only by the Byzantines, but by the Mohammedans of Persia, Syria, Egypt, etc. The Persians developed an especially important school of fine architectural brickwork which culminated in the Sufi period (1494-1600) and in which enameled tiles were used for the richly colored exterior decoration. The Byzantines soon sought to vary the plain brick exteriors by making a facing of alternate courses of stone or marble and bricks and by laying the bricks so as to form panels and patterns. Churches thus constructed begin to be numerous in the ninth and tenth centuries (e.g., the Theotokos, Constantinople, the Apostles, St. Bardias and St. Elias, Salonica, Misra churches). It was Byzantine art which invented decorative brickwork, for that of the Romans was always perfectly plain. Hence it passed into the Romanesque art of Italy in the eleventh century, through such monuments as Santa Fosca, at Torcello, and San Donato, at Murano. Thence arose two really decorative schools of brick architecture—the earlier and finer in northern Italy, the second in northern Germany. It is true that there is considerable good brickwork in the south of France. Its largest monument,

St. Sernin at Toulouse, is partly of brick, and the convent of the Jacobins, at Toulouse, is a most artistic brick structure, and wall patterns were sometimes obtained here by bricks of different colors, or a mixture of stone and brick, especially during the Renaissance. But Italy remained preeminently the home of brick construction, and the Lombard school solved the problem of combining it with details in marble and terra cotta, as well as by inventing a wonderful variety of molded bricks. Its results still serve as models. Mr. Strutt's book, *Brick and Marble Architecture of the Middle Ages in Northern Italy* (London, 1855), came as a revelation of possibilities. Pavia, Bologna, Cremona, Milan, Bergamo, Brescia, Verona, Vicenza, and many more cities are full of churches and town halls built entirely in this style, between the eleventh and sixteenth centuries. The style reached its culmination in the Gothic period of the thirteenth and fourteenth centuries. The different materials were variously combined. In the Merchants' Exchange at Bologna the shafts, tracery, and balcony are of marble, the capitals and archivolts of terra cotta, and the rest of brick, but in many cases most of the detail is obtained purely by pressed bricks. Brickwork was used also in Tuscany, Umbria, the Roman States, and in other regions, but not as generally or effectively. Spain also used it largely in the region between Saragossa and Toledo, and so did Flanders. But it was in northern Germany, especially in Brandenburg and Pomerania, that a second original note was struck, throughout the Middle Ages and the Renaissance, in such cities as Lubek, Hamburg, Brandenburg, Stralsund, Jerschow, Breslau, etc. The great gate towers are imposing, the churches and houses are characterized by gables—often stepped—of enormous size and a single pitch. There is less variety and richness of detail than in Italy, less combination with marble and terra cotta.

During the sixteenth century the use of brick in architecture made considerable advance in France, and during the seventeenth in England. The east wing of the Chateau of Blois, built during the closing years of the fifteenth century, ushered in the adoption of brick in monumental secular buildings, of which another early example is seen in the charming Manoir d'Ango. Under Henry IV, brick and stone were used together, the stone in quoins and for window dressings, and this practice has continued to the present time. At Fontainebleau and Versailles there are parts or adjuncts of the royal palaces built in this way, the reign of Louis XIII was especially prolific in such structures. In England the use of brick, previously confined chiefly to the fillings of half-timber structures, extended rapidly under Henry VIII, as in the earlier Hampton Court buildings, the St. James's Palace, etc. Under Queen Elizabeth and James I it became a common material for even the larger manor houses, and the introduction of the Italian style under Charles II did little to arrest this progress. A majority of the "Queen Anne" mansions are of brick, which in the eighteenth century nearly drove out the use of stone except for the most important monuments. But brick was handled with less artistic skill in England than in France. In Italy the artistic use of brick declined in the Renaissance, there are few if any late works of importance in this material. In the United States

brick was, until about 1880, employed only for ordinary routine construction, for backing stone-faced walls, and for private houses and schools, but excellent work had been executed, both in the South and in New England and Pennsylvania during the Colonial period. With the revival of architecture that set in between 1876 and 1880, there began a remarkable development in the manufacture and use of both brick and terra cotta (q.v.) and there is no country that commands such an extraordinary variety of kinds, colors, and forms of both these materials as the United States, or where it is at present more artistically and sympathetically treated in the best architectural practice. See ARCHITECTURE. For bibliography, see BRICKWORK.

BRICK CLAY. A term applied to almost any kind of plastic clay or shale of low grade. Such a clay shows a high percentage of fusible impurities and burns to a red or buff color. Brick clays are very widely distributed, underlying large areas in many parts of the United States and other countries, and belonging to a wide range of geologic formations. See BRICK; CLAY.

BRICKLAYING. See BRICKWORK; BUILDING, MASONRY.

BRICKS WITHOUT STRAW. A novel by Alphon W. Tourgée (1880).

BRICKWORK. The art and trade of building with brick; also the product of this art. The articles BUILDING and BRICK describe the nature and uses of this material and the history of its use; this article is concerned only with the technic of the art, which is one of the oldest of all the arts of building.

The essential quality of brickwork, which distinguishes it from all forms of stone masonry, is due (a) to the small and uniform size of the units; (b) to the mortar which cements them into a homogeneous fabric; (c) to the color of the bricks and sometimes also of the mortar. The small size of the units (in modern work generally 8×4 or $4\frac{1}{4} \times 2\frac{1}{4}$ or $2\frac{1}{2}$ inches) makes them easy to handle and creates possibilities of the greatest variety of texture in the surface of the wall, while their regular shape enables the bricklayer to build rapidly and to bond securely. By the use of thick or of close joints (showing respectively more or less of the mortar), by the use of tinted mortar, by different arrangements in the courses of bricks, and by the use of bricks of different colors and textures, it is possible to produce a remarkable variety of effects even in a smooth wall surface.

The chief essentials of good brickwork are of course excellence of materials and excellence of workmanship. Good bricks are of good clay, thoroughly burned, of the desired color, regular and uniform in size and shape. The mortar or cement must be of the right composition and consistency (of sand and lime, sand, lime, and cement, or sand and cement. See MORTAR; CEMENT). The workmanship must be such as to produce perfectly straight horizontal mortar joints of the proper thickness; vertical joints properly "broken" (i.e., not continuous through successive courses, but accurately aligned vertically), and a perfectly vertical face to the finished wall or pier. Moreover, in order to secure solid and homogeneous masonry, the bricks must be well bonded. *Bonding* is the laying up of the bricks in such manner that they interlock and thus tie all the parts of the work into a homogeneous structure. A *stretcher* is a

brick laid parallel to the face of the wall, a *header* is one laid at right angles to the face of the wall. In the face of a wall, therefore, a *stretcher* exposes its long edge, a *header* its end. A *closer* is a fraction of a brick less than a half-brick, inserted to complete a course whose length is not an exact multiple of the brick sizes. In *English* bond the courses are alternately of headers and stretchers; in *Flemish* bond each course is composed of alternate headers and

FIG. 1. COMMON BRICK BONDS.

stretchers. In the common *American* bond each sixth or seventh course is composed of headers, the other courses of stretchers. (See Fig. 1.) *Clip* or *diagonal* bond is laid up by clipping off the corners of the stretchers diagonally, and laying diagonal bonding bricks into the notches thus provided: this method does not show on the facing, which is composed wholly of stretchers. There are other methods of bonding, but these four are the most common. In the best work the facing and backing are laid up together with frequent bonding; but where the facing is laid up with close or fine joints and the backing less carefully with heavier joints, the courses of backing and facing do not "range" or reach the same level except at intervals of many courses, unless split bricks or clips are used in the backing. Hence in such work strap-iron anchors, bedded in the mortar of the horizontal joints, are sometimes used to tie the facing and backing together; but this does not bond them together into a monolithic unit, as is the case when all the work is laid up with equal courses well bonded together. Chimney flues, pipe chases, fireplaces, oblique corners, and circular structures require especial care and skill in forming them; so also the shaping of splayed or stepped window and door jambs and the building of arches and vaults. Usually the window boxings and the rough frames of doorways are set up in place and the brickwork built up to them. Arches and vaults are built upon dismountable wooden frames or molds called *centrings*, removed after the mortar has hardened or "set."

Brick arches are laid up in superposed concentric half-rings of headers, called *voussoirs*, which are in some cases bonded together by long radial stretchers at regular intervals, but arches in the facing are often laid up entirely of radial stretchers, or *voussoirs*, ground to the proper radial taper (Figs 2 and 3) Where

FIG 2 TYPICAL BRICK ARCHES

FIG 3 FLAT BRICK ARCH

stone quoins and window dressings are used with brickwork or stone facing with brick backing, it is desirable to make the stone courses range with specific numbers of brick courses, for this purpose the thickness of the mortar beds between the brick courses must be specified, this is done by requiring a given height for so many courses of brick, as 5 courses to 13 inches, or 9 courses to every 2 feet, or 8 courses laid up not to exceed by more than 2 inches the height of 8 courses piled dry. As the laying up of the facing of the wall proceeds, the mortar joints are either *struck*, i.e. carefully dressed by a stroke of the trowel, or *raked out* to a depth of a quarter- or half-inch, to be later *pointed up*, i.e. filled with finer mortar of the right whiteness or color, which is then either struck or in some cases molded into a slight relief.

Special forms of brickwork employ specially trained bricklayers among these are the hollow-brick flat arched fillings between the beams of fireproof floors (see FIREPROOF CONSTRUCTION) and various other constructions with hollow brick and tiles, the building of circular chimneys, the laying up of decoratively patterned wall facings, the setting of enameled brick and tile wall linings and wainscots, and the construction of GUSTAVINO, VAULTING. See GUSTAVINO, VAULTING.

Bibliography For modern American practice, consult many articles in the *Architectural Record* and the *Brickbuilder* periodicals, also Kidder, *Building Construction and Supervisance* (New York, 1900), and Magnus, *Bricklaying* (an excellent little handbook) (New York, 1900). For European practice and history of the art, Chabat, *La briquerie et la terracotta* (Paris, 1886), Degen, *Les constructions en briques* (ib., 1860), Street, *Brick and Marble in the Middle Ages* (London, 1874), Gruner, *Terra-Cotta Architecture of Northern Italy* (London, 1867), Stehl, *Der Backsteinbau romanischer Zeit in Oberitalien und Nord-*

deutschland (Leipzig, 1898), Essenwein, *Norddeutschlands Backsteinbau im Mittelalter* (Carlsruhe, 1855), Runge, *Beiträge zur Kenntnis der Backsteinarchitektur Italiens* (Berlin, 1885), Mitchell, *Brickwork and Masonry* (London, 1908).

BRIDE, BRIDAL, brī'dal (AS *brīð*, betrothed, OHG *brāt*, Icel *bráðir*, bride, Goth *brāths*, daughter-in-law, cf Gk *νύμφη*, *nymphē*, daughter-in-law, bride—probably from *brūn*, to cook, brew, make broth, in allusion to her duties in the primitive family) The word 'bride' is common to all the Germanic languages, as well as to Welsh (Ger *Braut*, Welsh *pryd*), and signifies 'betrothed' or 'newly married'. Alone, the word denotes the newly married woman, with the addition of the syllable *groom* (a corruption of *guma*, Lat. *homo*, a man), it denotes the newly married man (AS *brīðguma*, Ger *Brautigam*). Bride is the base of a variety of terms connected with marriage, as "bride favors," "bride cake," etc. Bridal is for *brideale* (AS *brīðeal*, the marriage feast). Bridesmaids, or attendants of brides, appear to have been customary among the Anglo-Saxons and are mentioned in early accounts of marriage ceremonies. A part of their duty consisted in dressing and undressing the bride.

Bride Favors are small knots of white ribbon which are pinned to the breasts of those who are in attendance at weddings. The origin of the bride favor is said to be the true lover's knot—something symbolical of the union of hearts and hands on the occasion.

Bride Cake is also symbolical in its origin. The ceremony used at the solemnization of marriage among the Romans was called *confarreatio*, in token of a lasting union between the man and wife, with a cake of wheat or barley (*far*). This is still suggested in that which is called the bride cake used at weddings. The old English and old Scottish custom of breaking a cake over the head of a bride on entering the new dwelling perhaps points to a usage of the most remote antiquity—the sprinkling of wheat as a token of plenty.

BRIDE OF ABYDOS, THE A narrative poem by Byron, described as a "Turkish Tale" (1813). Its rough draft was written in four nights, and 200 lines were later added. It was adapted for the stage by Dimond five or six years afterward.

BRIDE OF LAM'MERMOOR, THE A novel by Sir Walter Scott, further described as "a legend of Montrose." It is one of the *Tales of My Landlord* series and was published in 1819. Calcraft's (Cole's) *Bride of Lammermoor* and Mervale's *Ravenswood*, both dramas, were taken from it, as was the libretto of Donizetti's opera, *Lucia di Lammermoor*. See ASHTON, LUCY. Consult *London Monthly Review*, vol. XXIX, p. 387.

BRIDE OF MESSINA, THE (*Die Braut von Messina*) A tragedy by Schiller, founded on the *Œdipus Tynannus* of Sophocles, produced at Weimar, March 19, 1803. It is technically one of Schiller's most finished works.

BRIDE OF THE RHINE A name sometimes given to the river Moselle.

BRIDE OF THE SEA A name of Venice, referring to the traditional rite of marrying the city to the Adriatic Sea in medieval times.

BRIDEWELL A well between Fleet Street and the Thames, dedicated to St. Bride, which has given its name to a palace, parish, and house of correction. A palace, described as

"a stately and beautiful house," was built there in 1522 by Henry VIII, for the reception and accommodation of the Emperor Charles V and his retinue. King Henry himself also often lodged there, as, for instance, in 1525, when a Parliament was held in Blackfriars; and in 1529, while the question of his marriage to Catharine was argued. In 1553 Edward VI gave it over to the city of London, to be used as a workhouse for the poor, and a house of correction "for the strumpet and idle person, for the rioter that consumeth all, and for the vagabond that will abide in no place." Queen Mary having confirmed the gift, it was formally taken possession of in 1555 by the Lord Mayor and corporation. The Bridewell was afterward used for other persons than the class above named, and at last became a place of punishment till its removal in 1864.

BRIDGE. An artificial stream crossing; an elevated crossing in any location; a roadway across a river, giving passage below to the stream, or over a road, valley, or other land area, provided the structure has openings through it so that it consists of isolated supports and (one or a succession of) openings or *spans*. Generally a bridge carries a road or a railway; but it may carry a canal or water conduit (*aqueduct bridge* or *aqueduct*), or may support power-transmission shafting or a conveyor, the character of the structure being the same in all these cases. A bridge extending over dry land alone, or crossing at considerable height above a wide valley containing a relatively small stream, is usually called a *viaduct*, but this term is not specific. *Culvert*, a passage for a drain or small brook through an embankment, is related to bridge. An arch bridge made very short and wide, its width considerably exceeding its span, becomes a culvert. Constructively a culvert is so narrow (or represents a bridge of such short length) that very simple means of spanning the opening suffice, e.g., a stone lintel slab or stone or concrete vaulting of short span. In railway and road work culverts of greater width than 5-8 feet are classed with bridges.

Elementary forms of bridges are: a log or set of logs laid across a brook, resting on the two banks; an arch spanning between the rock walls of a gorge; a footpath laid on ropes stretched from bank to bank of a narrow valley. Such forms (the arch very rarely, however) are found among primitive races, and in the wilds are occasionally provided by nature (a fallen tree trunk bridging a stream, a rope of vines connecting trees on opposite banks). The bridge of one span is an outgrowth of these. The stepping-stone causeway improved by laying sticks or saplings to connect the stones is the prototype of the bridge of several spans. Wooden piles driven into the river-bottom soil to form bridge supports intermediate between the banks enabled the log or beam structure to be adapted to wider streams (trestle bridge or trestle, a form still widely employed for wooden bridges across valleys or across streams where passage of ships does not need to be provided for). The same principle of arrangement with use of boats for intermediate supports produces the *pontoon bridge* (e.g., the crossings of Darius, Xerxes, Alexander, over the Bosphorus, Hellespont, Euphrates), used even to-day in isolated cases. Piers built of stone, as intermediate supports for the wooden carrying members, make an advanced type of wooden-beam bridge.

Bridges were built by the most ancient races known to history. Wooden-beam bridges appear to have been the only kind known to the ancients (except the Chinese, who knew the arch and built stone-arch bridges) until the Roman age. The Romans used the arch very extensively in bridge construction; their best specimens existing to-day are in the great aqueducts built in Italy, Gaul, and Spain. Wooden-beam bridges were constructed in large numbers, especially in the earlier centuries, and later probably also wooden arches (Trajan's Danube bridge), besides the more elaborate and permanent stone arches.

The development of bridge construction for the next 10 centuries was the continued application of the stone arch for permanent or monumental structures and the wooden-beam type (nearly always on stone piers or stone-filled wooden cribs) for cheaper bridges. There being no railways, only roads and the few aqueducts required bridges. Feudal lords and governments usually constructed them, but bridge privileges were often farmed out to private parties, who built the bridge and took toll of the traffic over it. One or two orders of monks specialized in bridge building.

Leonardo sketched truss bridges, and Palladio probably built several. Two semitruss bridges were built in Switzerland about 1760. These attempts were preparatory to the truss invention and development of the nineteenth century. Cast iron was used for arch bridges as early as 1779, when Abraham Darby built a cast-iron arch over the Severn at Coalbrookdale, England. The use of cast iron (cast in pieces adapted to be set together like arch blocks or voussoirs, but in two or more separate ribs instead of in full arch barrel as with stone) extended considerably in the next 50 years, one of the best examples being Southwark Bridge over the Thames, London, 1819, with spans up to 240 feet. Timber truss-bridge construction did not develop, as the nature of the truss was not well understood, until about 1800, and not much until the railway era (after 1840). Combination trusses of arch rib and truss frame were invented in America about 1800, by Burr, true trusses by Palmer (1804), Long, Town, Howe (1840), Whipple, Bollman, Fink, Pratt (1844), and others. About 1800, also, suspension bridges using chains laid over towers on the banks, supporting a level roadway by hanger rods from the chains, were built by Finley in America and later (1814-23) by Brown and Telford in England.

The needs of railways now brought inventions and development marking the birth of the modern bridge. The first bridge wholly of wrought iron was built in 1823 over the Gaumless River, England, but wrought-iron bridges did not find extensive use till 30 years later. Plate-iron tubular bridges were built in England by Robert Stephenson (Memai Straits), 1847-50, and truss bridges were made efficient and economical in America. The wooden truss, and wooden trusses with iron tie-rods, led to combination cast- and wrought-iron construction (about 1850), and later to wrought-iron trusses. The latter depend on rolled plate, shape iron, and rivets for connection. Iron-bridge building then experienced high development, the full theory of truss-bridge construction and practical details being worked out; all other forms of bridge took a very subordinate position after 1860, and cast

iron was practically abandoned after 1870. In the middle of the eighties rolled steel took the place of rolled wrought iron and is now exclusively used. Beginning about 1905, nickel steel (steel alloyed with a small amount of nickel) has been employed in some of the largest bridges, where its superior strength is of decided advantage.

Soon after 1890 concrete came to be used rather extensively for arch-bridge construction. Reinforced concrete (concrete with imbedded steel rods, the steel taking tensile stresses and the concrete compressive stresses) also was developed, and several systems of arch reinforcement were exploited. Great advance in reinforced-concrete practice since 1900 has brought about the use of reinforced-concrete beams or solid girders, and occasional use of trusses, besides developing extensively the knowledge and practice of arch construction in reinforced concrete. In this short period the stone arch, after several thousand years' supremacy in the construction of permanent bridges, has been largely displaced by the arch of concrete and reinforced concrete.

Progress of the Bridge-Building Art. Length of span is an approximate measure of difficulty of achievement in bridge building. The ancients did not exceed spans of 100 feet with their masonry arches. To-day this type (including here concrete arches) has progressed to 328 feet. This advance is small enough to suggest the inherent limitations of the type. The characteristic bridge of the modern era, however, the steel bridge, has been built in spans exceeding 1000 feet, the greatest being the cantilever truss bridge over the Firth of Forth, Scotland, whose maximum span is 1710 feet (1890). The Quebec cantilever bridge over the St. Lawrence River, spanning 1800 feet, more than one-third of a mile, was begun in 1911. These figures are to be compared with 30 or 40 feet, the greatest spans of the ancients' simple beam bridges. However, from another viewpoint the comparison of span lengths is wholly inadequate to express the difference between ancient and modern bridge work, since the fundamental elements of modern civilization, the use of power machinery and large-scale working of iron, are essentially concerned in bridge building of to-day.

GENERAL ANATOMY OF THE BRIDGE

A bridge consists of main carrying frames, supports, anchorages, lateral bracing (wind bracing), stiffening or sway bracing, and roadway structure (floor). The floor is usually an independent part, which can be removed without affecting the stability or integrity of the bridge, the other parts, however, must be in combination to make the structure stable and give it strength. Supports of stone or concrete belong to the foundation or *substructure* of the bridge, the other parts constituting the *superstructure*, or bridge proper. Steel or wooden supports (as viaduct towers, posts or towers of suspension bridges, etc.) are included in the superstructure. **Roadway.**—The road crossing the bridge requires pavement, a railway requires rails, ties, and supports for the ties in canal and other special bridges corresponding elements are necessary. The supporting members of the floor, which transfer the roadway loads to the carrying frames, comprise usually longitudinal

beams (*stringers*) on which the planking or other floor slab rests, and transverse beams (*floor beams*), which carry the stringers and whose ends are attached to the carrying frames (tusses, girders, or the like). The type and detail construction of the floor have direct influence on the arrangement of the bridge. Traffic requirements determine the kind of floor used.

Carrying Frames.—These correspond to the log or vine rope of the aboriginal bridge. While a single log might do as a river crossing for savages, any other form of roadway demands at least two carrying frames side by side some distance apart (tubular bridges, see below, are an exception). In actual bridges there are normally two, less frequently three, four, or more, if two, they are near the outer borders of the floor. Their exclusive function is to resist vertical actions. The kind of carrying frame employed (beam, truss, arch, suspension cable) characterizes the bridge. In the stone arch the arch barrel, which is the carrying portion, is usually a unit, though one of considerable width, it may be regarded as a plurality of narrow arch rings set close together and firmly interconnected. Modern concrete arches (and some stone arches) have two (or three) separate arch rings, like the tusses of a steel bridge, connected and stiffened laterally by transverse members, the same arrangement is found in steel arches.

Wind Bracing.—The carrying frames, being long, narrow, and high, lack stability and rigidity and offer little resistance to wind pressure, centrifugal forces (if the roadway is on curve), and lateral vibration. Bracing connecting them supplies such resistance. The primary lateral bracing, wind bracing, is always a horizontal truss, or its equivalent. The lateral bracing of a steel bridge consists of transverse struts between opposite tusses, at intervals, and crossed diagonals in the resulting rectangular panels, which arrangement is typical of all forms of wind bracing. Such bracing is often applied at both top and bottom edges of the carrying frames (in the planes of top and bottom chords of the main trusses), but sometimes only in the plane of the roadway, or of the compression chord, or of the chord which bears most directly on the supports.

Sway Bracing.—Bracing in transverse vertical (sometimes in inclined) planes is used to supplement the wind bracing and stiffen the structure against longitudinal twisting and, in the case of a single plane of wind bracing, to extend the wind-bracing effect to the plane of the other chord. In truss bridges it is usual to place at each post of the truss a brace frame of crossed diagonals and transverse struts called *sway frame*, when these frames are above the roadway, they extend only part way down the posts and are *partial frames*. The principal portal frames are those at the ends of the span (over the piers or supports), where the lateral pressure of the upper wind truss must be transferred down to the supports.

Supports and Anchorages.—The end supports of a bridge are its *abutments*, which name originally applied to the end supports of arches. The abutments usually have to retain the earth of the approach roadway, besides supporting the bridge. Intermediate supports are *piers*, or, if two or more simple posts, they are called *bents* (posts in a single transverse plane), or *towers*. Wood trestle bridges rest on bents of wooden

frames or driven piles; steel bridges sometimes have intermediate bents or towers (in high viaducts usually the latter). Stone or concrete piers are of the usual type. They are founded below the surface of the soil or river bottom at such depth as to reach strata of adequate bearing power and are built with width of base and thickness of body sufficient to enable them to resist all forces transmitted from the bridge. (See ABUTMENT; FOUNDATION.) Steel bents or towers used as bridge supports are themselves supported on masonry piers extending above ground or water level. Timber bents, if not composed of driven piles, rest on a row of piles, or sometimes on a simple transverse distributing beam or *mud sill* below ground. The carrying frames do not rest on the piers and abutments directly, but *shoes* or *bearing plates* are interposed to distribute the bridge load over a sufficient area of the masonry; they often have rocking or sliding surfaces to allow for small movements of the bridge due to deflection, temperature expansion, etc. Shoes are of cast iron or cast steel, or are riveted steel assemblages. Short bridges may have simple flat steel bearing-plates in place of shoes.

*Anchorage*s hold the bridge in place (ordinary bridges), resist uplift (cantilever bridges), or resist outward pull and uplift (suspension bridges). The former are simple vertical anchor bolts fastening the shoes to the piers and abutments. Cantilever bridges have anchor bolts or bars of large size carried down into the abutments far enough to engage a large mass of masonry. The same applies to the anchorages of suspension bridges, except that the bars or bolts are usually inclined and the arrangement is elaborate in proportion to the large pulling forces to be resisted.

SERVICE OF THE BRIDGE

Primarily a bridge has to support vertical loads—its own weight (*dead load*) and the variable traffic loads (moving load, *live load*) and the weight of snow. It must also resist wind pressure, which acts horizontally (sometimes exerts a lifting effect), and in the case of railway bridges the longitudinal push or drag due to the arrest of momentum of a train when the brakes are applied. These are definite quantities which enter numerically into the design. Two other important agencies attack the structure: variations of atmospheric temperature, causing the bridge to expand and contract (or, sometimes, distort from its normal shape); and the disintegrating influence of exposure to the weather, which destroys paint, rusts iron, rots wood, and dissolves stone and mortar. Temperature effects are mechanically provided for in the construction of the bridge, or, where they produce stresses in the bridge (arches, suspension bridges), the stresses are computed and extra strength is provided to resist them. Consideration of exposure or weathering often leads to choice of steel over wooden construction, or stone over steel, and also affects various details of the design. The bridge must transmit all the loads to its supports and must not be overstressed in any part under any possible loading or under any influences which may act on it. The proportioning to this end is the *designing* of the bridge; it is based on *stress analysis* from pre-determined loading on the bridge and *maximum permissible unit stresses* in the material.

Loading.—Since bridge traffic is fortuitous and variable, the bridge must be built for the probable greatest traffic load and the most unfavorable grouping of loads. Road or street bridges (*highway bridges*) may have to carry crowds of people, wagons, droves of animals, or special vehicles as traction engines, road rollers, motor trucks, street cars. For crowds of people 100–125 pounds per square foot floor area is a maximum for bridges. For road rollers and traction engines the weights found in the locality where the bridge will be built are taken, usually 10 to 20 tons (freight carts and motor trucks rarely exceed 5 tons). Street cars weigh 20 to 40 tons. A close sequence of heaviest vehicles may occur under exceptional conditions; the floor area outside the vehicles may at the same time be crowded with people. Railway loadings (in America, those of Europe being lighter) range up to 5000 pounds per lineal foot on one track, besides the concentrated load of the locomotive. The heaviest locomotives weigh 6000 pounds per lineal foot, and the heaviest axle load is about 65,000 pounds. The effect of the separated axle loads of the locomotive is more severe than that of the same load distributed, and therefore the actual wheel loads and spacings of the heaviest locomotive which may cross a bridge are used by the bridge engineer.

Wind pressure reaches 20–25 pounds per square foot in violent gales, but in tornadoes may reach 50 pounds and may exert uplift. Bridges are commonly designed to resist a pressure of 25 pounds per square foot on bridge and vehicles, and 50 pounds on the empty bridge (wagons and railway cars are overturned at 20–30 pounds' pressure). Longitudinal or braking forces in railway bridges may amount to from $\frac{1}{4}$ to $\frac{1}{2}$ of the weight of the train. The temperature fluctuations which may affect the bridge depend on the type, e.g., in temperate climates a massive stone arch may not experience more than 50°–70° F. maximum range, while a steel bridge is subjected to the full range of atmospheric temperature, 100°–120° F.

Impact is the abnormal stress-increasing effect of a load moving over the bridge with jarring, pounding, or vibration. A very light and flexible bridge vibrates under the step of a small party of men, and experiences stresses greater than the same load would produce if quiescent. The motion of a railway train contains many irregularities in its rolling, and in addition the lack of perfect balance in the locomotive mechanism entrains vertical oscillations, all increasing the effect of the train on the bridge. Bridge engineers allow for these abnormal effects by adding material to the parts of the bridge, under empirical rules. Numerous experimental studies of impact effects in bridges have been made, notably by Prof. F. E. Turner, but the subject is not yet on a final basis. A common rule is to double the stresses caused by live load; for long spans this rule is modified by reducing the allowance one-half in spans as long as 300 feet and still more for longer spans; impact effects are known to be most severe in short bridges, and the rule given is known to be safe. Impact allowance depends vitally on the trained judgment of the engineer.

BRIDGE MATERIALS

Until within a century and a half the only materials used for bridges were wood and stone,

except for occasional brick arches. Wood was used for the piles and cribs of the foundations, for main beams and flooring of beam bridges, and in rare cases for the voussours of arches. Stone was used in the piers (both in the form of masonry and as irregular stone filling of foundation cribs) and in the arches. Design was not based on stresses, as knowledge of the mechanics of structures was primitive, yet experience gave sufficient skill to produce fairly efficient and economical bridges.

Stone in bridges is stressed only in compression. The crushing strength of even weak building stone is adequate, durability, ease of working, etc. are more important considerations. Sound limestones and sandstones, and granite, are most used. The compressive stress on the stone should be limited to 250-500 pounds per square inch. High stresses require special attention to the bedding and the mortar joints. Strong cement mortar should be used.

Wood—All structural timbers are suitable for bridge construction. Yellow pine is most used to-day. Unit stresses of 800-1200 pounds per square inch in compression along the grain, 1000-1800 in tension, and 50-250 in shear, are employed. Shear along the grain and compression across the grain are special factors of weakness. However, deterioration is so large a feature in the life of wooden bridges that low-unit stress is most advantageous in bridges exposed to the weather. Covered bridges have stood 100 years (Waterford Bridge over Hudson River, burned 1909) with little decay.

Cast Iron—This first new material of the modern-bridge period has high compressive strength and low tensile strength and is brittle under blows. It is suited to compression only, and is now used only for angle blocks in wood-and-iron Howe truss bridges and for shoes. (A few bridges of concrete with cast-iron core have been built recently.) Stresses of 15,000-20,000 pounds per square inch are allowable.

Wrought Iron—Used in nails and bolts of bridges since early times, wrought iron was first employed as the exclusive material of a bridge in 1823, and then only in rare local instances until the Menai Straits tubular wrought-iron bridges were built by Stephenson in 1847-50. High tensile strength, toughness, and the possibility of building firm assemblages of it by riveting parts together make it an excellent bridge material. Wrought iron has a tensile strength of 48,000-55,000 pounds per square inch and a compressive strength (in columns) of about 27,000 pounds per square inch. Its shearing strength is intermediate between the two values, and therefore rivet connections can be made compact and efficient. Tie-rods with forged or threaded ends can be made for any requirement. Wrought iron in bridges may be stressed to 12,000 pounds per square inch in tension and compression, and 7500 in shear. It would be the prime bridge material to-day but for the perfecting of steel-making processes. Mild steel is very similar to wrought iron, but even stronger, and in the past quarter-century has been the cheaper. About 1885 it displaced wrought iron.

Steel—Bridge steel, unlike tool steel, is always mild or medium steel, containing only 0.10 per cent to 0.30 per cent of carbon. It has a tensile strength of 56,000 to 68,000 pounds per square inch and a column strength of 28,000 to 33,000 pounds per square inch, is fully as

tough and plastic (or ductile) as wrought iron, and is capable of use for rivets. Plates of steel are nearly equally strong with and across the grain, while wrought iron is weak across the grain of rolling. The iron bridges of to-day are all of steel. Allowable unit stresses are noted below.

Nickel Steel—Mild steel alloyed with 2 to 4 per cent nickel has been used in some of the largest recent bridges. It is 50 per cent stronger and has all the good qualities of ordinary bridge steel. For the same strength nickel-steel bridge parts are much lighter, hence in bridges whose dead load makes up the most important part of the total load (long-span bridges) the use of nickel steel reduces materially the entire load which must be supported (Manhattan Bridge, New York, Municipal Bridge, St. Louis, Cologne Suspension Bridge, Germany, and others).

Concrete—The Romans used a concrete made of ground volcanic tuff, lime, sand, and broken stone or bricks for much of their later building, including bridge construction, always with stone or tile facing. Modern concrete is very much stronger and more uniform and reliable. It is made of Portland cement, sand, and gravel or broken stone, for bridges usually mixed in the proportions 1 2 4 (by volume), then wet to pasty or soupy condition, put in place in wooden forms and allowed to harden (3-30 days) before the forms are taken down. Its crushing strength is 1500-3000 pounds per square inch. Arches experience (generally) only compression, yet are usually reinforced with steel, beams, floor plates, etc., which carry tensile stresses, always have steel rods bedded in the concrete in such a way that the rods resist the tensile stresses. The steel does not rust subsequently. The concrete is practically as permanent as stone. A few arch bridges have been built of concrete blocks molded to shapes and sizes similar to those of the stone blocks used for stone arches.

BRIDGE UNIT STRESSES

(For mild steel, nickel steel, and concrete. Approximate averages from practice, pounds per square inch.)

	Compression	Tension	Shear
Mild steel	15,000-18,000	15,000-22,000	10,000-12,000
Nickel steel	15,000-30,000	30,000-40,000	15,000
Concrete	500-700		100
Steel in reinforced concrete	10,000	15,000-20,000	10,000

(Adhesion to concrete 50 to 100)

Compressive stresses must be taken lower in columns, increasingly so for long columns (see COLUMNS), various other kinds of stress must be computed and allowed for, the above table giving only broadly characteristic figures.

BEAM BRIDGES

The aboriginal log bridge continued through ancient and mediæval times as the bridge of hewn logs or beams, and still exists in the timber trestle, the short-span bridge of steel I-beams or plate girders, and the reinforced-concrete beam (or girder) bridge. Moreover, the truss is merely a skeletonized beam, and its action in a bridge is similar to the action of an ordinary beam. Truss bridges also use solid beams as important subsidiary elements, since

the smaller space-spanning parts, the floor members, are beams.

Solid-Beam Bridges. Railway and highway crossings over small streams, 10-20 feet wide, are still often made by timber beams. A road bridge of this kind is sketched below, and the section of a railway bridge is also given (Fig. 1). The differences in arrangement of carrying beams in the two cases depend on the differences in the floor, the latter being suited to the traffic requirements. Sometimes gravel or broken-stone metaling is placed on the floor planking of road bridges, and a similar type of floor is occasionally used also for railway bridges, the ties being bedded in the ballast.

Trestle Bridges are combinations of several such beam bridges placed end to end, supported

FIG. 1.

by wooden pile or framed *bents*. Trestles are still in very extensive use on American railways, though generally on the older and more important lines most of them have been replaced by more permanent bridges (steel, stone, concrete). The life of a timber trestle does not often exceed 10-15 years, on account of decay. Many trestles also are destroyed by fire, starting from brush fires or from live coals dropped out of a locomotive fire box. Trestles to-day are often built of wood impregnated with creosote, as a protection from decay; this increases the fire danger. Ballast on plank flooring has been used on some railway trestles.

Action of the Beam. A stick laid across two supports and pressed downward by a load bends. Its upper fibres are shortened and its lower fibres are stretched, and exert corresponding internal forces (*stresses*). Intermediate fibres experience stresses intermediate between these extremes, and at or near midheight of the beam there is no longitudinal stress (*neutral plane*). These stresses are the action of one part of the beam on the adjoining part. If the left-hand half of the beam be cut away from the right-hand part, forces must be applied to the cut faces in exact equivalence to the pre-

viously existing stresses, in order to hold the separated parts in place. For the left-hand part this is sketched in Fig. 2. The group of com-

FIG. 2. ACTION OF THE BEAM.

pression and tension forces opposes the *external bending moment* or tendency of load and reaction (of the support) to turn the beam downward at the right. At the same time the vertical force along the cut face balances the excess of load over reaction. These two stresses—(1) the compression-tension group of forces or the *resisting moment*, and (2) the *shear*—are the most important quantities in the analysis and design of beams. For the formulas used in proportioning beams, see *MECHANICS*.

Steel I-Beam Bridges. The most effective resistance to bending is offered by the fibres farthest from the neutral plane of the beam, as may be inferred from the sketch above. By massing the material of a beam at upper and lower edges, leaving only a narrow web down the middle, a beam of maximum efficiency is obtained. The rolled steel I-beam is of this form; it has greater bending strength per square inch of cross section, hence makes a stronger beam out of a given amount of material than any other shape. The production of rolled wrought-iron I-beams about 1840 was an essential factor in the evolution of the wrought-metal bridge. For dimensions of rolled shapes, consult rolling-mill handbooks, *American Civil Engineers' Pocket Book*.

I-beam bridges are precisely similar in arrangement to the timber-beam bridges described above. They are used as railway bridges up to 20-25 feet span and as highway bridges up to 30-40 feet span. Such bridges usually have lateral bracing of single-angle diagonals and struts connecting the upper flanges of the opposite beams or sets of beams; this bracing resists lateral distortion of the bridge which might result from swaying of the load or from wind pressure. It also holds the upper flanges of the I-beams against *bulging* under their longitudinal compression.

Plate-Girder Bridges. The plate girder extends the application of the beam bridge very greatly; plate-girder railway bridges are used in great numbers, and spans of 130 feet are in use (Erie Railroad and others). The plate girder is a large built-up I-beam, the largest rolled I-beams being 24-30 inches deep. The construction of plate girders and their disposition in a bridge are shown by Fig. 3. The similarity to smaller beam bridges is patent; but because of its size and loading a plate-girder bridge involves certain considerations which are negligible in smaller bridges but are controlling in all large bridges.

Deck and Through Bridges.—Beam bridges always have the decking or floor resting on the beams, but in plate girders, while this is the preferred arrangement, the floor may also be located between and near the bottom of the girders, and be carried by subsidiary beams

riveted to the sides of the girders, as in Fig 3. Where head room under the bridge must be high, without raising the bridge floor, such a *through bridge* is built. The *deck bridge*, with floor resting on top of the girders, has much simpler floor construction, especially in railway bridges. The typical railway deck plate-girder bridge has the cross-ties laid directly on the top flanges of the girders, there being thus no floor framing, the girders are directly beneath the rails or nearly so (5 feet apart), except that girders as long as 100 feet are set farther apart (8-9 feet) for stability and lateral stiffness. A through-girder bridge must have the girders set far enough apart to admit railway trains (12-15 feet), and therefore requires complete floor framing, including lateral bracing between the top flanges of the stringers. In such a bridge each panel of the floor is an independent I beam bridge, supported by attachment to the

employed at both fixed and expansion ends (in the latter, over the rollers), to avoid any canting-up effect as the girder deflects under load.

Questions of Erection arise with plate-girder spans. Small beam bridges are built together at the shop, and shipped and erected as one piece, but with the large plate-girder spans this is usually impossible. Commonly each girder is shipped as one piece, set in place with a derrick or other hoist, and the floor and bracing put in last. Some large girders are not riveted together to their full length in the shop, but are shipped in two or three pieces, which at the bridge site are set on temporary wooden supports (*falsework*), so as to be in correct final position, and are then riveted together. However, girders 120-130 feet long have been shipped in one piece.

Tubular Bridges—The first important wrought-iron girder bridges were great rectangular

FIG 3 SINGLE-TRACK RAILWAY PLATE-GIRDER BRIDGE

floor beams. This difference in floor makes the through-girder bridge more costly than the deck bridge for railway use. In highway bridges the difference is less, on account of the width of the floor, a full floor framing being used even in the deck bridge.

Bracing—In ordinary beam bridges bracing is negligible, in plate-girder bridges it must be carefully provided, and there must also be sway bracing to hold the high, narrow girders against tipping or twisting distortion. The latter consists, in deck bridges, of brace frames in vertical transverse planes, in through bridges of triangular plate brackets connecting each floor beam with the side and top flange of the girder. Lateral wind trussing must be used in both deck and through bridges, in addition to the stringer laterals, it is not shown in Fig 3.

Expansion—On account of the length of span expansion must be provided for. The girders are bolted to their bearing only at one end of the bridge, and the other end has either smooth-planed bearing plates or a set of rollers between upper and lower plates, permitting the bridge to slide longitudinally, with very long spans, special pin or rocker shoes (see Fig 3) are

used. In these bridges the roadway is completely inclosed in the tube, floor and roof act as flanges, the side walls as webs, the former are cellular, with top and bottom plates inclosing longitudinal I-shaped stiffening ribs, while the side walls are single plates stiffened by angle bars. The Victoria Bridge over the St Lawrence River at Montreal (240-330 feet span) was built of the same type (1854 replaced by a truss bridge, 1897). The type is obsolete.

High Viaducts—Plate-girder construction finds special application to long and high railway bridges over wide valleys, where earth embankment is not applicable. Such structures are formed of a succession of plate-girder spans resting on steel towers, each made up of four columns set at the corners of a rectangle, braced together. The top of each tower is itself occupied by a plate-girder span. Usually the intermediate spans are made about twice as long as

the *tower spans*. The longest spans are in a high viaduct of the Canadian Pacific Railway 314 feet above the Belly River valley, Canada, where 100-foot intermediate spans are employed. Viaducts are erected without falsework, by a traveling hoist working on the railway track and overhanging forward the full length of one span. This traveler works from one end; it lifts and sets in place the members of the tower just ahead, then lifts the intermediate span to place, and so progresses forward. The simplicity of this erection method is a main reason for the use of the plate-girder type of viaduct. A few notable high viaducts are listed below:

SOME HIGH STEEL VIADUCTS

Name	Date	Height	Length
Los, Bolivia	1888	336	800
Goktek, Burma	1900	335	2260
Pecos	1861	321	2180
Lethbridge	1909	314	5327
Kinross	1882	301	2053
Verrugas	1872	250	575

Reinforced-Concrete Girder Bridges. This type of beam bridge, a recent development, consists of a reinforced-concrete floor slab on (usually) two reinforced-concrete girders. The girders are designed for bending moment and shear like all beams, and the floor slab is similarly calculated. (See REINFORCED CONCRETE.) The floor slab also serves as lateral bracing, in wide bridges it has a supporting frame of floor beams and stringers similar to floor arrangements used in steel bridges. While many bridges of this type have been built, arch construction is generally preferred when reinforced concrete is used.

TRUSS BRIDGES

Early Trusses. Two rafters tied together at the foot by a wood or iron tie form the simplest truss. The old Romans used this and also some more elaborate forms in roofs. Knowledge of roof trusses was not applied to bridge construction, however, except possibly by Palladio and by Leonardo, in Italy. In a truss (Fig. 4) each member is stressed only in direct tension or compression, hence utilizes the full strength of all its material, while in the beam the interior fibres are only partially stressed. In this fact lies the advantage of the truss. However, truss bridges were not developed from a recognition of this truth, but in their beginnings were evolved empirically, scientific study following.

FIG. 4. EARLY ROOF TRUSS.

struction, however, except possibly by Palladio and by Leonardo, in Italy. In a truss (Fig. 4) each member is stressed only in direct tension or compression, hence utilizes the full strength of all its material, while in the beam the interior fibres are only partially stressed. In this fact lies the advantage of the truss. However, truss bridges were not developed from a recognition of this truth, but in their beginnings were evolved empirically, scientific study following.

FIG. 5. BEAM REINFORCED WITH TRUSS ROD.

Beams reinforced by truss rods (Fig. 5) were used in bridges occasionally in the eighteenth century. The Rhine bridge of Grubenmann at Schaffhausen (1756) was a compound timber beam with auxiliary corbel beams of arch-like

character, the main beams absorbing the thrust of the arch. In 1764 he built a wooden solid-rib arch bridge with stiffening truss across the Limmat, Switzerland. The arch-and-truss combination appeared again in the bridges of Burr (Fig. 6), who constructed a number in the

FIG. 6. BURR TRUSS.

United States about 1800, closely similar to the Limmat bridge. Truss bridges not involving an arch were invented soon after by Palmer, Long, Town, Howe, Whipple, Pratt and others. The *Town lattice truss* (1829) became very popular, its closely spaced web system (Fig. 7) permit-

FIG. 7. TOWN LATTICE TRUSS.

ting the chords to be loaded at any point, like a beam; but bridge analysis was not advanced enough to permit correct design of details in such an intricate truss. The *Howe truss* (1840) was the first permanent one, being still in wide use. It comprises upper and lower horizontal members (*chords*) of wood, vertical iron tie-rods at intervals, and crossed diagonal struts of wood between successive rods. (Fig. 8.)

FIG. 8. HOWE TRUSS.

With angle blocks at the ends of the diagonal struts satisfactory details were secured. The Howe truss is specifically adapted to timber and is not used with iron. The *Pratt truss* (1844) is excellently suited to iron, on the other hand. In place of the vertical tension rods of the Howe, it has vertical posts, and in place of the diagonal struts it has tension rods (Fig. 9). The

FIG. 9. PRATT TRUSS.

main diagonals are those inclined downward towards midspan, the opposite diagonals (*counters*) being required only near the middle of the bridge, to take tension when the bridge is loaded on one side only. It did not become popular for wood-and-iron construction, but became the main type with wrought iron. The modified Pratt truss is the prevailing type of bridge truss to-day. Special importance attaches to the

FIG. 10. WHIPPLE TRUSS.

Whipple truss because Whipple wrote (1847) the first work on truss analysis in America, as well as because his form of truss was used extensively up to 1890; though no longer built, many examples of it are still in service

(Fig 10) It is intermediate between the lattice and the Pratt, having a double system of diagonals between the chords (hence called a double-intersection truss, multiple-intersection trusses were also built with three web systems, four, etc., up to a sufficient number to make

FIG 11 WARREN TRUSS

them lattice trusses) The *Warren truss*, with a single web system having no verticals, successive diagonals sloping in opposite directions, also came to the front in the middle of the nineteenth century (Fig 11) The Howe, Pratt, Whipple, and Warren trusses initiated the modern era of bridge construction

Parallel Chords were most used in trusses at first Later, trusses made deeper at midspan (where the bending moment is greatest) by giving one or both of the chords a curved or polygonal outline were brought out The bowstring truss, with a straight bottom chord joining the ends of a parabolic top chord, appeared early,

Bollman Truss

Fink Truss

Curved Chord without Subdivided Panels.

Curved Chord with Subdivided Panels

FIG 12 TWO EARLY AND TWO MODERN BRIDGE TRUSSES

originally as an arch with tiebeam, but later provided with web verticals and diagonals, making the truss complete The curved-chord truss without pointed ends, obtained by arching up the top chord of a parallel-chord truss, was later preferred and is the present standard for long spans

Long spans offer difficulties in the floor framing as the panel length increases The advantage of the Whipple truss of halving the panels was 20 years later secured in better manner by adding to a Pratt truss subsidiary trussing to form *subdivided panels* without affecting the simplicity of stress distribution

With curved chords and panel subdivision the iron-bridge truss achieved, broadly, its modern development, subsequent improvements have been mainly in details and in refinement of design. However, two other solutions of the long-panel floor problem were devised for the Forth Bridge and the St Louis Municipal Bridge In the former a complete inner subsidiary truss-bridge structure extends along from panel point to panel point, supported by transverse trusses at these points In the St.

Louis bridge, where even the subdivided panels were too long, the floor comprises main plate-girder longitudinals between the main floor beams, carrying secondary floor beams which support the stringers

Diagrams of some other truss types are shown in Fig 12

Action of the Truss The truss is a plane network of triangles whose bars are (in theory) connected by hinge points The triangle is a rigid figure, and similarly a net of two triangles (quadrilateral with diagonal) or of any number of triangles is rigid, supported at two points and loaded at any of the others, it will maintain its form except for minute deformations caused by the elastic extension and shortening of the individual bars The triangle network is seen best in the Warren truss (Fig 11)

Supported like a beam, on but two supports exerting (for vertical loads) only vertical reactions, a truss has determinate reactions, computed as for a beam, it is a *simple truss* Its stresses under any particular loading are easily determined When there are more than two supports, or when the supports are such as to exert nonvertical reactions of variable direction, their calculation depends on the internal structure of the truss, either (1) upon the presence of a hinge in the truss (cantilever truss, three-hinged arch), or (2) when there is no hinge, upon the elastic properties of the truss (constrained truss, continuous truss, arch of less than three hinges, suspension framework) The latter case (*indeterminate support*) requires intricate computations However, so soon as the reactions have been computed, the stresses in the truss are readily determined, provided the truss has no unnecessary (super-numerary) members, i.e., provided no member can be removed without causing collapse Trusses with supernumerary members are *internally constrained frames*, they are used infrequently.

The action of the truss in carrying loads is exhibited in the three sketches of Fig 13 In I, a bottom-chord member is removed, the two

FIG 13.

parts of the truss are free to move downward, as the arrows indicate, causing A and B to separate Evidently the member AB must exert tension to hold the truss together In II and III the diagonal CD is removed, in the first case points C and D separate, in the second

they approach, showing that the diagonal CD (when in place) holds the truss rigid by exerting tension in the one case and compression in the other. Most web members of trusses are subject to the same condition as CD , viz., they must resist tension at one time and compression at another (stress reversal). Where such a member is a wooden strut whose ends butt against the other members at the joint and cannot receive tension, or where it is a thin iron tension rod incapable of resisting compression, the arrangement seen in the middle panels of the Pratt truss (Fig. 9) is used; an opposing diagonal is added to the panel, and one or the other diagonal is alone in action at any one time, depending on the position of the loads. The added diagonal is a *counter*. The Howe truss is usually built with counters in all panels (timber-strut diagonals), and then the vertical tie-rods can be tightened up initially, making all joints tight. The Pratt truss, with rod or eyebar diagonals, has counters in the panels near the middle only; the others experience no stress reversal, because the dead-load tension is great enough to overcome the live-load compression.

Analysis of Stresses. Truss stresses may be computed by composition and resolution of forces, as shown in elementary statics, so soon

FIG. 14.

as the reactions have been computed. In Fig. 14 the reaction force R may be resolved in two directions parallel to the two members $0-1$ and $0-2$, and since the forces acting at the joint must form a balanced group the stresses in these two members will be equal to the computed components (but of opposite direction). Proceeding in this way for successive joints, all stresses may be obtained. This process is the basis of *graphical stress analysis*. This consists in drawing a force polygon and a string polygon (see GRAPHIC STATICS) to determine the reactions, and then drawing a *reciprocal* or *Maxwell* diagram, which is a continued application of the triangle of forces and thus is the graphical expression of the above-stated method of computation; the stresses are measured from the diagram.

Numerical stress analysis is done generally by the method of sections, based on the principle that, since any segment of the truss is in equilibrium, the stresses at its ends must balance the combined effect of loads and reactions on that segment. In Fig. 14 the stress in the top-chord member $4-6$ is obtained thus: Cut the truss by a section indicated by the irregular line, and at the cut faces of the members $4-6$, $4-5$, $3-5$, apply forces equal to the stresses which existed in those members; then the entire left-hand segment of the truss must be in equilibrium, all forces balancing. If panel point 5 be taken as fulcrum (centre of moments), the turning moment of the loads resting on the segment and of the reaction R is easily computed; and since the stress in $4-6$ exerts a balancing moment, it is found by dividing the moment by the lever arm d of stress $4-6$. Or, to find the stress in the diagonal $4-5$, cut the truss in

the same way and compute the net vertical force acting on the segment (equal to load W less reaction R); this is equal to the vertical component of the stress in $4-5$.

The cross-sectional area and strength of connections which a member must have are determined from the stress by simple division, knowing the stress per square inch which is permissible in such a member. At this stage the engineer must, by computation or judgment, allow for all accessory influences which may require greater strength in the member, e.g., vibration, tendency of compression members to buckle, etc.

The above principles of analysis, applied with much systematization of detail, are employed for all trusses. Trusses with multiple web system like the Whipple and the lattice are internally constrained; in practice approximative assumptions are made concerning the division of load between the several web systems, and thereafter the methods above outlined are used.

Influence Lines.—A diagram representing the variation of stress in a given member of a truss as a single load moves over the bridge is called the *influence line of stress* in that member. To draw such a line, the stress for each particular position of the load is to be laid off vertically below the load, from a horizontal base line. Influence lines are used in determining the position in which a specific group of wheel loads (e.g., a locomotive) will produce maximum stress in the particular member for which the influence line was drawn. These positions may also be derived by algebraic analysis.

Details of Truss Bridges. The steel truss depends essentially on riveted plate-and-shape assemblage. The larger part of bridge material is plates and angles, with channels next in importance. Bridge rivets are small steel pins, $\frac{3}{4}$ inch to 1 inch in diameter and 2-8 inches long as required by the thickness of the plates to be joined. The various plates have holes punched or drilled in them, matching when superimposed, to receive the rivets. The rivet has a head formed on one end beforehand; it is heated to bright heat, inserted in the hole, and then upset at the other end to form a second head. The plates are held tight between the two heads of the rivet and are drawn still tighter together as the rivet cools. *Pin connections* and eyebar tension members were universal in American practice until about 1890 and are still used in all bridges of great size, while English and European practice employ *riveted connections*. In pin-connected construction a joint is made by a steel "pin," 3-24 inches in diameter, which passes through all the members meeting at the joint, their ends being interleaved for the purpose. In erecting the bridge a pin joint is connected by simply driving in the pin, while a riveted connection, consisting of large side plates, *gussets*, which extend over the sides of all the members and are riveted to them, must be temporarily held by screwing in a large number of bolts and later riveted up permanently. Since trusses have in theory frictionless hinge joints, a pure hinge action was claimed for pin connections by American engineers in former years; but it is now known that the friction on pins nullifies their hinge action. Both riveted and pin joints interfere with free angular distortion of the truss network (which occurs as the load stresses slightly extend or compress the members) and

compel the members to bend slightly to suit the distortion. These bending stresses are *secondary stresses*, their calculation, practiced only during recent years, is now regarded as important in the design of all large bridges.

Rivets are never used for tensile, but always for shear-resisting action, holding plates against being pulled apart by slipping past each other. They are designed on the basis of their shearing strength and the bearing power of the edge of plate against which they bear. However, their real holding effect is in the friction between the plates due to the tight grip of the rivets.

Eyebars are wide bars forged at the ends to disk-like heads in the plane of the bar, through which holes are bored to fit the joint pins. They are highly reliable tension members, and their full sectional area is active without loss by rivet holes. Eyebars have been made as large as 16 inches by 2 inches and 50-70 feet long, capable of bearing 250 tons' tension, in a very large bridge the tension chord and main diagonals may have 8 to 12 such bars side by side.

Bracing of truss bridges is arranged as already described and is made nowadays of rigid plate-and-angle members, connected to the trusses with riveted joints.

A few long-span simple-truss bridges are listed below.

SOME LONG-SPAN SIMPLE-TRUSS BRIDGES

CONTINUOUS AND CANTILEVER BRIDGES

Two successive spans of a bridge have greater strength if then girders or trusses are con-

I Two Simple-Span Girders

II Continuous Girder

III Cantilever Arrangement of Girders

FIG. 15

noted at top and bottom so as to become *continuous*, the bridge then has continuous girders or trusses (see I and II, Fig. 15). The action

of such a bridge is disturbed by lack of perfect adjustment in erection, and later by settlement of any support, and therefore the type is little used in bridge construction (swing bridges are a modified application). Stephenson's tubular bridges (see above) were continuous girder structures. The largest recent bridge of continuous type is the Fades Viaduct, France (1904-08), with three spans totaling 1228 feet, the middle one 472 feet long and 435 feet above the valley bottom.

In the continuous girder the *points of contraflexure*, or reverse bending shift slightly as the position of the load shifts. A hinge in the girder as at III fixes the location of the contraflexure, the structure then is a *cantilever bridge*, which has the economy of the continuous girder but avoids its disadvantages. The reactions of cantilever bridges are computed by use of the lever principle as with simple beams and trusses, and the stresses are then readily found, reactions and stresses do not depend on the make-up or the elastic properties of the bridge.

Besides economy the cantilever bridge has advantage in ease of erection when a span not containing a hinge has been erected, the hinge span can be built by adding on member after member, without using falsework, since in each successive stage the bridge is self-supporting. Cantilever construction has been used for the world's longest bridges, and only the suspension type is a near rival. A list of some large cantilever structures is given below.

LONG CANTILEVER BRIDGES

Name	Railway or Highway	Date	Span, ft
Quebec	Ry		1800
Forth	Ry	1890	1710
Blackwells I., New York	Hy	1908	1182
Sakur, India	Ry	1889	820
Wabash, Pittsburgh	Ry	1902	812
Memphis	Ry	1892	790
Beaver	Ry	1911	769
Mingo	Ry	1902	700

The famous Firth of Forth Bridge, designed by Baker, completed 1890, is the most remarkable of the group. It is unique among modern bridges in having its members made up of great tubes built of plate iron, instead of rectangular members riveted together of shapes and plates, and also in having all its parts built together out of the elementary plates in place.

Quebec Bridge and K-Truss. An 1800 foot cantilever across the St. Lawrence River near Quebec, was begun in 1903, and collapsed in 1907, when its south half was nearly completed. The failure is not chargeable to the cantilever principle, but was due to imperfections in details, the main compression chords of the anchor arm buckling under some 6000 tons compressive stress each. A new bridge of the same span, 1800 feet, was begun in 1911. Its design (Fig. 16) employs an unusual type of truss, the *K-truss*, which is a modified Pratt truss with the advantages of the Whipple truss in short panel length and ease of erection.

ARCH BRIDGES

A bridge which presses outward against its supports is an arch bridge. An arch is essentially a compression member, a curved strut

pressed together by the abutment reactions and held down by the loads on it. Under a particular fixed loading the curvature of the arch can be so adjusted to loads, span, and rise that the compression is central (axial) everywhere along the arch (*linear arch*), but for any other loading the compression is no longer axial, and the stresses then are the equivalent of an axial stress and a bending moment. Therefore, bridge loads being shifting, bridge arches must have considerable stiffness against bending. They are of either beam or truss construction: *solid-rib arches*, and braced arches or *arch frameworks*. The former are built of stone, concrete, steel; the latter always of steel.

The invention of the arch cannot be dated with certainty, the Romans probably having derived the arch from a prior race. While arch construction has been practiced continuously for over 2000 years, its science has been devel-

two-hinged arch, of simpler nature. An additional hinge at the crown converts this into a *three-hinged arch*, a type which is as easy to analyze as a simple truss or a cantilever bridge. Two beams set on end and brought together at the top form an elementary three-hinged arch. A fourth hinge destroys the stability of the structure.

Theory and Analysis.—When the reactions (thrusts) are known, the arch stresses can be analyzed by methods similar to those used for beams and trusses. This process is usually employed for arch framework. For solid-rib arches, however, a special form of graphical analysis is commonly employed. Drawing the load forces and the reactions to scale in their true locations, a string polygon is drawn, starting at one of the reactions; this polygon represents the *line of pressure* in the arch ring. The distance at any point from pressure line to mid-

FIG. 16. OUTLINES OF OLD AND NEW QUEBEC BRIDGES, ST. LAWRENCE RIVER.
(The Old Bridge collapsed during erection, 1907.)

oped only within the past century and a half; but experience had taught efficient stone-arch construction before the science was worked out.

The arch in all forms consists of a barrel or *ring* (or *ribs*), bearing against skewback blocks of the abutments at its ends (the *springing lines*), and rising to the *crown* or *key*. The portions between skewbacks and crown are the *haunches*. The inner and outer faces of the ring are *intrados* or *soffit*, and *extrados*. The height from springing to crown is the *rise*; generally a flat arch (with low ratio of rise to span) is more difficult in construction than a high arch. Arches are named as to form: elliptical or basket-handle, semicircular (full-centred), segmental (circular, less than half a circle), parabolic, pointed (Gothic), three or five-centred (approximating elliptical form but made up of arcs of circles).

Types. Apart from differences in material and outline, arches differ in their nature with the number of hinges they contain. The ordinary stone or concrete arch has no hinges, but forms a continuous rib rigidly anchored to the abutments or bearing against them with broad end faces; it is the most complex type, the *fixed arch*. Hinges at the abutments make it a

depth of arch ring, multiplied by the amount of the arch pressure at that point (scaled off the force polygon), is the bending moment which acts in the arch at that point; computing (by the beam formulas) the stresses caused by this moment, and adding the compressive stress which the arch pressure would cause if central to the ring, gives the edge stresses in the arch.

The lever principle is sufficient for determining the reactions in three-hinged arches. With centre of moments at one abutment the opposite vertical reaction is obtained; with centre of moments at crown hinge the horizontal thrust is obtained. Two-hinged and fixed arches involve the flexibility of the arch, as follows: If the end supports be changed to vertical supports (eliminating the arch thrust), the arch spreads, by an amount depending on the position of loads and on the flexibility of the arch. The amount of spread can be computed; also the thrust which will reduce the spread by one inch can be computed; the number of inches spread multiplied by the thrust per inch gives the thrust which is exerted on the actual arch. This is sufficient for two-hinged arches, but an additional computation is needed for fixed arches. In the actual arch the part adjoining

the skewback does not change its angular position. Regarding the arch as two-hinged, the change of angle at the skewback can be computed, for a given position of the loads, and also the end moment required to reduce the angular change one degree, this moment multiplied by the degrees of angular change for the two-hinged condition gives the actual end moment of the fixed arch.

For solid-rib arches the above considerations lead to three formulas by which the thrust and end moment are found

$$\int \frac{M ds}{I} = 0, \quad \int \frac{M x ds}{I} = 0, \quad \int \frac{M y ds}{I} = 0,$$

in which M = bending moment at any point of the arch, in terms of the loads and the unknown reaction, thrust and moment, I = moment of inertia of the cross section of the arch at that point, ds = element of arc length of the arch ring, x = horizontal distance of the point from one abutment, and y = vertical distance of the point above the plane of the skewbacks, the integration being extended from abutment to abutment in each case. For fixed arches all three formulas are used, for two-hinged arches, only the last two. The three equations express the following facts: angular change at abutment is zero, vertical displacement at abutment is zero, and horizontal displacement at abutment is zero. For arch frameworks the same reasoning but different resulting formulas are used, involving summation and the stresses in the members in place of integration and the ring moments. The *reciprocal theorem* serves for finding the deflections and is the basis of the formulas, the *principle of least work* is often employed instead.

Besides load effects, temperature effects must be calculated in two-hinged and fixed arches, as the end constraints interfere with free expansion (or contraction) and therefore stress the arch. In flat arches the temperature stresses are a large fraction of the total stresses.

Stone and concrete arches sometimes are fitted with hinges (two, rarely three), but in the vast majority of cases they have no hinges, hence are fixed arches and should be analyzed by the methods just referred to. In recent practice this is often done, the result being to locate the pressure line at the abutment, whence the string polygon continues it through the length of the arch. A simpler and satisfactory method, widely used, bases on the principle that the true pressure line is that one which departs least from mid-depth of the arch ring, various string polygons, starting at different points of the skewback, are drawn in such a way as to strike near the middle of the key of the arch, and the one which diverges least from the centre line of the ring is accepted as the true one. The principle is safe only for arches carrying solid spandrel walls, and may be applied only with great care to *free-rib* arches, where the roadway is supported on the ring by isolated columns. For arch analysis, consult Merriam and Jacoby, *Roofs and Bridges*, part III, Howe, *Symmetrical Masonry Arches*, and A. Treatise on Arches, Cain, *Graphical Arch Analysis*.

In designing an arch the distribution of dead load is first studied, and the curve of the centre line of the ring is made to correspond as nearly

as possible to the linear arch for the dead-load distribution. The intrados curve may depart from this shape to suit the desired aesthetic effect, but the ring thickness must be correspondingly increased. Then pressure lines or stresses are computed for various groupings of the live load. For both stone and concrete arches the governing principle is to keep the pressure line within the *middle third* of the ring thickness, as this assures that no tensile stresses occur (masonry is not suited for tension).

Metal Arches. The Coalbrookdale cast-iron arch of 1779 was followed in the nineteenth century by the construction of a large number of cast-iron arch bridges. These of London and Paris are the most notable. In their nature they are direct analogues of the stone arch, being formed of a ring of arch blocks. They are built on centring and are subject to the limitations of span length affecting the masonry arch. Cast-iron arches exceeding 200 feet in span have been built, and proposals have been made for very much larger ones. However, the two greatest cast-metal arch bridges are of cast steel—the Eads Bridge over the Mississippi (1874), of 520-foot span, and the remarkably flat three-hinged Alexander III. Bridge over the Seine in Paris, with a single span of 353 feet and a rise of but 20.6 feet. Wrought-metal arch construction outdistanced cast construction, however, as may be seen from the table below, giving steel

arches over 500 feet in span. They are of two essentially different forms—rib arches (e.g., Eads and Washington), and arch frameworks. The former are built with plate-girder ribs, the latter of chord-and-web arrangement like that of trusses but of different outline. The two Niagara arches exemplify two important arrangements of arch frameworks. The lower arch, 550 feet in span, has a parabola lower chord and a horizontal upper chord, the upper arch has parallel chords, both being curved. The famous Garabit arch in France (1885) has crescent-shaped framework.

The main spans of the great arch-shaped Rhine bridges at Dusseldorf, Bonn, and Cologne are not arch but truss bridges, having a tension chord and exerting no thrust against the abutments. They are listed above with simple-truss bridges.

Stone and Concrete Arches. The stone arch has much historical importance, but to-day it is used infrequently for bridges. Works on the history of bridges (e.g., Tyrrell, *History of Bridge Engineering*) may be consulted for descriptions of old stone arches. The greatest constructive feat in stone arch building was the

bridge over the Adda at Trezzo, Italy, about 250 feet in span, built 1380, destroyed 36 years later. A 295-foot arch at Plauten, Germany (1903), is the longest ever built. Some others are noted below:

Grenoble, France (1611)	160

Concrete has been used for arch construction since about 1890; at first stone arch types were followed, but in the early nineties steel-reinforcement was applied, permitting bolder design, and since then the concrete arch has become essentially differentiated. The arch ring is divided into two or more narrow ribs some distance apart laterally, braced together by struts, and columns resting on these ribs carry a floor of reinforced-concrete girders and floor slab. In such bridges the unit stresses cited under *Materials* are the basis of design, and with accurate analysis of the elastic deformations of the bridge very economical design is achieved. Concrete arches have been built as large as 328-foot span; some large-span arches are listed below. None of these are hinged. The largest hinged concrete arch is at Gruenwald, Germany, 230-foot span (1904).

Use of the Arch.—An arch may be considered as derived from the truss by combining the functions of compression chord and web and omitting the tension chord. The latter item is an economy unless very expensive abutments outweigh the saving of tension member. The

arch, therefore, is best adapted to a rock-gorge location, or wherever the arch thrust is easily transferred to solid foundation strata. Also the elevation of roadway above valley must be high enough to admit the rise of the arch, flat arches being the most costly.

Building a stone or concrete arch bridge is done by first erecting a temporary supporting scaffold, of wood or steel (centring), with a board floor in the line of the arch intrados, and laying up the stone or molding the concrete on this floor. The centring is later lowered (struck), using wedges, sand-boxes, or jacks; the design of centring is a special problem. The centring distorts slightly under load, and precautions are used to avoid cracking the new masonry.

SUSPENSION BRIDGES

Following the pioneer chain suspension bridges of Finley in America (e.g., Greensburg, Pa., 1801), probably the first with floor hung from the cable, many suspension bridges

were built in Europe and America, wire ropes as well as chains being used. A chain suspension bridge of 676-foot span over the Thames at London (1845) and a wire-cable bridge of 1010-foot span over the Ohio at Wheeling, W. Va. (Ellet), were the greatest. Roebling built the first suspension bridge with *stiffening trusses* over the Niagara River in 1855 (825 feet), using many parallel wires assembled into large circular cables as the carrying members, and in 1863 built a 1057-foot bridge over the Ohio at Cincinnati. Keefer built the noted 1260-foot Clifton Bridge over the Niagara River in 1868. The building of the Brooklyn Bridge over the East River at New York (1869-83), with a span of 1595½ feet, carried by four 15½-inch parallel-wire cables, gave the suspension bridge great fame; this was the longest bridge span of its time. Two equally great suspension bridges were built near the Brooklyn Bridge 26 years later, the Williamsburgh and Manhattan bridges (1800 feet and 1470 feet); they represent important constructional improvements over the Brooklyn Bridge, yet the latter has been in constant service 30 years and with minor reinforcement is carrying safely a traffic much heavier than originally intended. All three bridges have parallel-wire cables—the type which gives greatest strength per pound. Eyebar-chain suspension bridges have also found important application, as notably at Budapest (1905), with 951-foot span, and at Cologne, where a chain bridge with plate-girder stiffening member was begun in 1913.

The action of a suspension bridge is that of a rope spanning between supports: for any loading it finds the appropriate curve of equilibrium and is stable in that position. But as the adjustment to varying position of load results from change of curve, the roadway hung from the cable also distorts, i.e., the bridge is very flexible. Longitudinal stiffening trusses are therefore used, their stiffness preventing any but slight distortion under localized loading. The stiffened suspension bridge is analogous to the Burr arch-and-truss combination, the cables (the arch) carrying uniform load, while the trusses take care of inequalities in loading. The numerical analysis of this action is intricate, however, depending on calculations of relative deflections. Various arrangements of the truss-stiffening system (with hinges at various points, without hinges, supported at foot of main tower, free of tower, etc.) are employed, which further complicate the design problem. Temperature expansion is another complication, altering the relations between cable and truss. The structure is made somewhat simpler by building the stiffening truss directly along the suspension chain, the latter forming part of the truss; such a bridge is an inverted arch and is analyzed by arch methods. Large bridges have not been built of this system hitherto, as wire cables have been preferred to eyebar chains, and the difficulty of attaching the inverted-arch trussing to cables leads to use of ordinary stiffening trusses.

Three essentially different types of suspension bridge are represented by the three East River bridges. Some of the differences are: the Brooklyn Bridge has stone towers, suspension carrying the roadway in both main and shore spans, shallow stiffening trusses, and auxiliary hanger cables sloping down from the tower tops to the roadway and carrying an indefinite

BRIDGES

2. THE COMPLETED STRUCTURE

part of the roadway load. The Williamsburgh Bridge has open-frame steel towers (built of posts and bracing), suspension cable loaded in main span only (the shore spans of the cables acting merely as backstays), deep and rigid stiffening trusses, and no auxiliary hangers. The Manhattan Bridge has solid plate-construction steel towers, roadway hung from the cables in both main and shore spans, deep stiffening trusses, and no auxiliary hangers. The two former have expansion roller bearings under the cable saddles on top of the towers, while the Manhattan Bridge has its saddles rigidly fixed to the towers, the towers being so high that they are able to bend slightly (and yet support their enormous compressive load) as the cables shift longitudinally under temperature and load changes.

Suspension bridges are few in number compared with tuss and arch bridges. Their special fields are very long spans (particularly for highway bridges, which do not have the intense localization of loading to which railway bridges are subject), and moderate spans of very light character, as footbridges.

MOVABLE BRIDGES

The movable bridge or drawbridge, which can open to pass ships and close to carry its own traffic, finds its prototype in the castle-moat drawbridge. On rivers with much shipping drawbridges must be highly efficient, i.e., open and close quickly, to offer minimum interruption to both river and bridge traffic. Much inventive ingenuity has been spent on drawbridges, many types of movable bridge are in use and many more have been invented. The three prevailing types will be described briefly, others have found only rare or exceptional application.

Swing Bridges are truss or plate-girder bridges resting on a central pivot or turntable and fitted with hand winch or power drive geared to a circular rack surrounding the pivot, by which the bridge can be swung in a horizontal circle. The pivot is sometimes near one end, giving only one channel (bobtail draw), the short end being counterweighted so that the bridge balances on the turntable. Ordinary central drawspans afford two equal channel openings. By far the most drawbridges are of the swing type (until about 1890 almost none others existed).

The structure of a drawbridge is designed and built like that of other bridges, but the girders or trusses must be adequate for two different conditions of support: (1) when swung away from the end supports, the bridge being a simple cantilever beam on a single central support, and (2) when resting on the end supports, being then a continuous girder on three supports (sometimes four, if the two edges of the turntable afford sufficiently rigid support to be counted as separate supports). The end bearings must, however, be at a height corresponding to the unstrained outline of the bridge, i.e., higher than the ends of the bridge when swinging, as the ends then sag down. This requires *end-lifting machinery*, consisting of wedge blocks or toggle members (rarely lifting jacks) between the shoes and the ends of the bridge, operated from the machinery at the turntable. The turntable may be *centre-bearing*, i.e., consisting of a pivot only, or of a pivot with a few balancing wheels arranged in a ring around it,

or *rim-bearing*, i.e., consisting of a large ring of wheels which carry the whole load. The variations in turntable and end-lift construction are numerous.

Swing bridges exceeding 500 feet in span have been built, providing channel openings up to 200 feet. Long spans are rare, however. The fact that the pivot pier of a swing bridge occupies the middle of the passage, the most valuable part for navigation, is a strong objection to the swing bridge, yet sometimes the advantage of affording two separated channels (for up and down ship movements respectively) is decisive in favor of the swing bridge.

Bascule Bridges are similar to the medieval lifting drawbridges, being spans pivoted on horizontal trunnions at the ends, or of equivalent arrangement. On account of the great weight of a bridge span their operation would be impracticable were they not counterweighted in such manner as to balance on the trunnions. The balance must be maintained in all positions of the bridge, which offers certain difficulties. The means by which balancing is attained determine the differences between the several types of bascule in use. The *simple bascule* projects back of the pivot, and the tail carries the counterweight below its floor, tail and counterweight swing down in a tail pit as the bridge is swung up. Gearing arranged in the tail pit is the usual means of operation. With use of parallel-motion linkage the counterweight can be placed above the roadway, and the tail pit thus eliminated, this construction, in various modifications, is used in the Strauss and Rall bascules, though the latter in place of trunnions has for each truss a small wheel as support for the bridge, the wheel rolling back as the wheel rolls on its upper surface. In the Scherzer or *rolling-lift bascule* (see view) the entire rear end of the truss itself forms a large half-wheel, which rolls on a horizontal track just back of the abutment, the centre of this wheel is the virtual trunnion, and as this point is high above the bridge floor the counterweight is above the roadway.

Bascules are single-leaf or double-leaf, the latter consisting of two single leaves trunnioned on the opposite banks and with the free or lifting ends butting at midstream when the bridge is closed. A strong *latch* must be fitted at the abutting ends to lock the two leaves together so that their deflections under load will be in unison. Single-leaf bascules are also latched at the lifting end, to prevent vertical oscillation or *hammering* under the vibratory impact of traffic. A bascule acts as a cantilever under dead load, being balanced on the trunnions, but under live load a single-leaf bascule is a simple span on two supports. Bascules have been built with length of leaf over 200 feet, openings larger than 150 feet are needed but rarely.

Direct Lift Bridges represent an old type, recently revived. The construction is simple. The ends of the lift span are hung to cables passing up over sheaves on the tops of towers, with counterweights on the ends of the cables (inside the towers) balancing the whole weight of the bridge. Lifting cables passing over other sheaves on the towers and pulled by winch machinery located in the tower or on the lift span serve for moving the bridge up or down. An advantage of this type of bridge is that the span need not be "opened" to its full extent in each operation as must a swing bridge,

but for a vessel of low height need be raised only part way, thus giving quicker operation.

MISCELLANEOUS BRIDGES

Pontoon Bridges. Bridges of boats have been used at various times for 2500 years, and some are in use to-day (Rhine at Coblenz; Golden Horn at Constantinople). Their advantage is the elimination of foundations and piers in the river. Such a bridge comprises a close succession of barges or *pontoons*, ropes and anchors to hold the pontoons in place, and beams or truss spans from pontoon to pontoon carrying the roadway. If heavy load concentrations have to be carried, the successive spans must be interlinked and so designed that the passage of the loads over the bridge will not produce an excessive wave motion of the structure. Modern pontoon bridges are built with steel pontoons and trusses. Usually a draw span is included, consisting of a pontoon-supported section which is either hinged at one corner to the fixed portion and at the other end can be swung out of line of the bridge, or else is completely free, like a boat, except when latched in place between the ends of the fixed portions; the draw may be operated by rope, by the current of the stream, by screw propeller, by a tow vessel, etc.

Ferry Bridges. A ferryboat hung above the water from a bridge spanning the stream at a high elevation (so that ships can pass underneath) makes up the modern type of structure called ferry bridge or transporter bridge. Only a few have been built. In most of them the bridging span is of the suspension type; a ferry bridge at Duluth, however, has a simple truss span of normal character supported on high steel-braced towers at its ends. A track hung under the bridge carries wheels (or a truck) from which the ferry platform or car is suspended either by ropes or by a stiff frame. The truck running on the bridge track is moved by pull ropes or by gearing, thereby moving the ferry car across the river. The first such bridge was built by Arnodin in 1892 at Bilbao, Spain (span, 525 feet). The longest is at Widnes, England, of 907-foot span, built in 1905. In the same year the truss structure at Duluth was built, of 394-foot span; except this latter, all ferry bridges are supported by suspension cables.

Composite Bridges. This article has described distinct types of structure, but these are sometimes used in combinations of two types, composite bridges. Except for special conditions such composite bridges offer no advantage, and they are not only uncertain in their stress analysis, but are subject to change of internal conditions later, whereby greater load may be thrown on one element of the combination and the bridge thus become less safe.

BRIDGE ERECTION

Only the smallest bridges can be set in place entire. Large steel bridges are built together of sections or pieces previously constructed (built, fabricated) in a bridge builder's shop. Stone and concrete bridges are laid up or molded in final position out of their elementary parts. The construction in final place is called *erection*. In most cases it involves the use of temporary supports in the stream or valley crossed, called *falsework* or (for arches) *contring*. The

detail operations differ, depending on the location and nature of the bridge.

Steel Bridges. Derrick cars or gantry crane-frames (*travelers*) are used for lifting and setting the parts. Where possible, plate-girder spans are built together complete at the shop, with bracing and floor, and the entire span is set in place by a derrick or crane which lifts it off the railway cars and sets it down on its piers. High plate-girder viaducts have each span erected in similar manner, but before setting a span the derrick must erect the tower ahead, nearly always by hoisting its individual members and setting them in place one by one, from the bottom up, the derrick must therefore have a long overhang. Simple-span truss bridges are usually erected on falsework, but occasionally by floating in, the span being built together on falsework along the river bank, or by cantilever erection (span anchored back to be self-supporting as a cantilever temporarily). The cantilever method is always used for cantilever bridges and often for arch bridges; for the former, one span (an *anchor span*) must first be erected on falsework like a simple span, the cantilever span then being built out without falsework; for arch spans temporary backstays must be provided to prevent tipping forward.

In erecting steel bridges the connections of members are made by driving pins or by bolting up (and later riveting) the connection gussets, as already mentioned under *Trusses*. The final step is to lower the falsework support, letting the bridge come to bearing; this is usually done by knocking out wedges previously placed in the falsework. Riveting was formerly done with hand hammers. Pneumatic hammers are now used almost exclusively; steel-bridge erection has been considerably facilitated by their introduction.

In simple or non-constrained spans the erection requires no adjustment of length of members, except that counter-diagonals fitted with turnbuckles must be tightened up to a bearing. Cantilever erection requires provision by jacks or wedges to lift the halves of the bridge before closure, by an amount corresponding to the sag, which during erection is different from that occurring in completed condition. Arches (except three-hinged) and all other constrained structures must have their closing sections fitted into place in such a way that the amount of constraint actually secured is the same as that on which the calculations were based. Thus, a two-hinged arch framework may be connected at the crown in the bottom chord without special precaution if the top chord is still open, but the subsequent closure of the top chord requires mean atmospheric temperature (that for which the arch was calculated as unstrained) and such load on the bridge as would according to the calculations result in zero stress in the closing member. This offers some difficulties: occasionally hydraulic jacks have been used to strain the bridge to the precise degree appropriate to the momentary load and temperature conditions. A common expedient in recent years for two-hinged arches is to make the closure by simple insertion at mean temperature, i.e., with zero stress in the closing member, and correspondingly to calculate the arch as though it were a three-hinged arch for the dead load and a two-hinged arch for live loads. Similar erection difficulties arising in other constrained bridges are dealt with by related methods.

BRIDGES

SCHERZER ROLLING LIFT (Bascule) BRIDGE, over Chicago River; open and closed.

MILITARY BRIDGES

1. PONTON BRIDGE.

3. SPAR BRIDGE.

2. SPAR TRESTLE BRIDGE.

Suspension-bridge erection varies with size of span and type. Small bridges usually have twisted-rope cables, which can be carried across, anchored at the ends, and laid on the towers without difficulty. Parallel-wire cables as used for the New York suspension bridges are built by the slow process of drawing wire after wire (each about $\frac{1}{4}$ inch in diameter) across from tower to tower and down to the anchorages, adjusting the position of each wire to the intended sag of cable, and, when all wires are in place, squeezing the mass of wires into circular form and binding it with a close covering of wire wrapping laid on spirally. A temporary suspension footbridge is first built by hauling ropes across the river, and on this footbridge the "cable-spinning" work proceeds. When the cables are finished, the hanger ropes are clamped to them, and last the floor members are hitched to the lower ends of the hangers, working out gradually from towers to midstream. Building the stiffening trusses is simple, as the floor affords a platform for this work, the trusses are not riveted up until completely reached, and until the proper temperature is reached, to avoid initial stress or constraint.

Stone and Concrete Arches. The centring for a large stone or concrete arch is itself of great magnitude and supports very heavy loads. Its design and construction must guard particularly against settlement, as the partly built masonry or concrete is injured by cracking if the centring settles or deflects before the arch is complete. For the same reason the load of the arch must be brought on the structure uniformly, so far as possible, to secure uniform deflection under load. To this end some stone arches have been built by laying up first a thin ring, the inner part of the arch, then another ring, etc. Usually, however, the arch is divided into numerous sections or arch blocks, and alternate blocks are constructed, thus producing uniform loading before any long portions of the ring are made continuous, the intermediate blocks are last laid up.

The design of bridges must consider the possibilities and economical methods of erection at all stages. Broadly a bridge design is determined as much by regard to erection as by any other consideration. Thus, where a stream or valley is so deep, or current or ice conditions so bad, that falsework cannot be used, a type of bridge must be chosen that permits erection without falsework, and generally, a bridge design of lighter weight may be inferior to a heavier one that is easier and cheaper to erect.

Renewal of Bridges. Bridge replacement is largely an erection problem. When a bridge must be replaced by a stronger or better one, the traffic often may not be interrupted, particularly on railways. The construction of the new bridge must be worked out with primary regard to the possibility of erecting it around, in, or alongside the old bridge without interfering with traffic, and so that at the end the traffic can be shifted from old to new bridge with no sensible interruption. On this account a bridge that has become too weak for the traffic (by increase of traffic load, introduction of street cars, etc.) is often reinforced, by addition of new trusses or by other means, though such work may be more costly and less satisfactory in result than the construction of a new bridge. The replacement of the Kentucky River Viaduct, the first cantilever bridge, in 1911 (consult *En-*

gineering News, vol. lxxv, p. 518), is a good example of replacement under traffic, and the reinforcement of the Point Bridge, Pittsburgh, in 1905 (*Engineering News*, vol. lxxi, p. 85), an example of repair and reinforcement.

Bibliography. The literature on bridge building is quite extensive and is widely scattered, much of the most valuable descriptive matter being found in the periodical literature of the engineering profession. Among engineering papers are *Le génie civil* (Paris, 1880, current), *Zeitschrift des Vereins deutscher Ingenieure* (Berlin, 1857, current), *Engineering* (London, 1866, weekly, current), *Engineering News* (New York, current), and the *Engineering Record* (New York, current). *The Proceedings of the Institution of Civil Engineers* (London, 1838, current), *Annales des ponts et Chaussées* (Paris, 1831, current), and *Transactions American Society of Civil Engineers* (New York, 1868, current), also contain much important information relating to bridges. Among the more recent textbooks and books of reference are Johnson, *Practice of Modern Framed Structures* (New York, 1900), Meriman and Jacoby, *Roofs and Bridges* (New York, 1900), Waddell, *De Pontibus* (New York, 1898), I. Hroi, *The Statistically Indeterminate Stresses in Frames Commonly Used for Bridges* (New York, 1905), F. C. Kuntz, *Design of Steel Bridges* (New York, 1914), W. Cain, *Theory of Solid and Braced Arches and Theory of Steel Concrete Arches* (New York).

BRIDGE. A game of cards similar to whist and formerly called bridge whist. It is played with a full pack of 52 cards and is a game for four persons. The game is 30 points. These points are made by attaching a certain value to each trick over six, according to the suit which has been declared as trump. Spades are worth 2 points, clubs, 4 points, diamonds, 6 points, hearts, 8 points, no trumps, 12 points. Besides the score for tricks there is a separate score for honors. Honors are the five top cards (A, K, Q, J, 10) of the trump suit, at a declared trump, or the four aces at no trump. The score for three honors between partners is worth twice the value of the suit declared, 4 honors, 4 times, 5 honors, 5 times, 4 honors in one hand, 8 times, 4 honors in one hand, 5th in partner's, 9 times, 5 honors in one hand, 10 times. At no trump 3 aces between partners count 30 points, 4 aces 40 points, 4 aces in one hand, 100 points. Chicane (holding no trumps) counts the same as three honors. Grand slam (taking all of the 13 tricks) counts 40 points, little slam (taking all but one trick) counts 20 points. The rubber is the best of three games, and if the first two games are won by the same partners, the third is not played. The winner of the rubber receives 100 points in the honor column.

Partners sit opposite each other, and their positions at the table are known as dealer and dummy, eldest hand and pone. The cards are shuffled and dealt as in whist, except that no trump card is turned. After examining his cards the dealer may declare any suit for trump that his hand warrants, or he may play the hand without a trump. As there is a great difference in the value of the declarations the dealer may make, he also has the privilege of bridging, or passing, the make to his partner. If this is done, his partner must make a declaration. After the trump has been settled,

the adversaries cannot change it, although they may increase the value of the points to be played for by doubling, in which case the dealer or his partner may redouble, and so on until both sides are satisfied. When the doubling, if any, is finished, the eldest hand may lead any card in his hand he pleases for the first trick. As soon as this card is placed, the dealer's partner must lay down in front of him on the table his 13 cards, face upward and sorted into suits. From that time on he becomes dummy, the dealer playing the exposed hand and his own without help or comment from the dummy. The dummy may call the dealer's attention to a revoke or to an incomplete trick. Consult: Foster, *Complete Bridge* (New York, 1908); Elwell, *Practical Bridge* (New York, 1908); Dalton, *Complete Bridge* (New York, 1906); Hingley, *Hints on Advanced Bridge* (London, 1910); Forbes-Lindsay, *Blue Book of Bridge and Auction for Beginner and Expert* (Philadelphia, 1911). See AUCTION BRIDGE.

BRIDGE, NATURAL. See NATURAL BRIDGE.

BRIDGE, OF A SHIP. A platform raised some distance above the deck of a vessel for the convenience of the officer having charge of the deck. In merchant vessels there is usually one bridge extending the full width of the ship; in some very large steamers there are two of this character. In men-of-war the bridges are reduced to the least possible limits in order to decrease the amount of *débris* which might accumulate in action about the conning tower. When a bridge expands into a platform of considerable area, instead of being merely a narrow promenade, it is commonly called a *bridge deck*. On some vessels there are as many as two bridge decks, one above the other, with the bridge or bridges above both. On or under these bridge decks the pilot house, chart house, and captain's cabin are usually placed.

BRIDGE, SIR FREDERICK (1844-). An English organist and composer, born at Oldbury (Worcestershire). He studied under John Hopkins and Sir John Goss, in 1865 was appointed organist of Trinity Church, Windsor, and in 1869 of Manchester Cathedral. From 1875 to 1882 he was deputy organist of Westminster Abbey, of which he was in the latter year appointed organist. He became successively professor of harmony in Owens College (Manchester), professor of harmony and counterpoint at the Royal College of Music, and in 1902 King Edward professor of music at London University. His works include: *Mount Moriah* (1874), an oratorio; two cantatas, *Bodicea* (1880) and *Callirhoc* (1888); a setting of Gladstone's Latin version of Tiplady's "Rock of Ages," *Lover of Music* (1904), and many anthems, including one for the celebration of the Queen's jubilee at Westminster Abbey (1887).

BRIDGE, HORATIO (1806-93). An American naval officer, born at Augusta, Me. He graduated at Bowdoin College in 1825, was admitted to the bar, and in 1836 was appointed paymaster in the United States navy. From that time until 1861 he cruised about, making several visits to Africa, which he describes in the *Journal of an African Cruiser* (1845). He was then made chief of the Bureau of Provisions and Clothing. Upon his resignation in 1869 he was appointed chief inspector in the same department and finally retired with the rank of commodore. He also wrote *Personal Recollections of Nathaniel Hawthorne* (1893).

BRIDGE, JOSEPH COX (1853-). An English organist and composer. He was born at Rochester, Kent, studied under John Hopkins, and from 1871 to 1876 was organist of Exeter College, Oxford. In 1877 he became organist of Chester Cathedral. In 1879 he revived the triennial Chester Music Festivals, which had been abandoned in 1864. His works include an oratorio, *Daniel* (1885); a *Magnificat* and *Nunc Dimittis*, in C, for voice and orchestra (1879); a *Symphony in F* (1894).

BRIDGE-BUILDING BROTHERHOOD (Lat. *Fratres Pontifices*). A religious fraternity formed in the south of France in the latter half of the twelfth century, to build bridges and keep ferries. As the Church considered such labors meritorious, the societies spread and grew rich. According to tradition, the shepherd boy, Bénézet, received a revelation that he must build a bridge across the Rhône at Avignon. Accordingly he went to the bishop and told his story, but was repulsed. The provost, however, aided him, and work was begun in 1177. The bridge was not completed until 1185, and Bénézet, dying in the meantime, was buried in the chapel in one of the columns of the bridge. He was afterward canonized. Either the fame of St. Bénézet, or compassion for persons who were forced to pay large tolls, led to the founding of a brotherhood for the purpose of carrying on the work of bridge building, and in 1189 Clement III sanctioned the order. Similar brotherhoods were formed in other parts of France and in the north of Italy. They labored very hard for a time, but soon the possession of wealth led to idleness. In 1277 the Brotherhood of Bonpas wished to unite with the Templars, but instead Nicholas III united the order with the Knights of St. John (1278). Other brotherhoods were active for nearly three centuries until the dissolution of the order by Pius II. Consult Grégoire, *Recherches historiques sur les congrégations hospitalières des frères pontifes* (Paris, 1818).

BRIDGEHEAD, or (in French) TÊTE-DU-POINT. In military engineering, a fortified work intended to defend the passage of a river over a bridge. See TÊTE-DU-POINT.

BRIDGEND, brî'end'. An industrial market town of Glamorganshire, Wales, 14½ miles southeast of Neath (Map: England and Wales, C 5). It is a junction of the Great Western Railway and lies on both sides of the river Ogwr. In the town are ruins of a Norman castle. In the neighborhood are the interesting remains of Ogmores Castle, of Coity Castle, and the castellated ruins of Ewenny Priory, founded in 1146. Blast furnaces constitute the chief industry. Pop., 1891, 4076; 1901, 6290; 1911, 8021.

BRIDGE OF SIGHS, THE. 1. A lofty bridge in Venice, built by Antonio Contino about 1595-1605. It spans the Rio della Paglia, connecting the Doge's Palace with the Carceri Prigioni. Its name was derived from the fact of its leading to the prisons. It is inclosed at the sides, arched overhead, and contains two separate passages. Byron mentions it in the opening lines of *Childe Harold*, Canto IV. 2. A poem by Thomas Hood (1844), on the recovery of the body of a London outcast, who had drowned herself in the Thames. 3. The name is also used of a bridge connecting the Tombs prison in New York with the court rooms.

BRIDGE/PORT. A city, port of entry, and

one of the county seats of Fairfield Co, Conn, on Bridgeport harbor, an arm of Long Island Sound, at the mouth of the Pequonnock River, 18 miles southwest of New Haven, 56 miles northeast of New York (Map Connecticut, C 5) It has railroad connections by the New York, New Haven, and Hartford and its branches, and steamboats run daily to New York The city is built mainly on level ground and occupies an area of about 15 square miles Black Rock, which forms part of Bridgeport, is a summer resort, its harbor being a popular anchorage ground for yachts The most notable buildings are the United States post office and customhouse, the county courthouse, the Barnum Memorial Institute, the Burroughs Public Library, the Sterling Widows' Home, the Burroughs Home for Aged Women, the Protestant Orphan Asylum, St Vincent's Hospital, the city hospital, a new high school, and the Young Men's Christian Association Building Bridgeport is the headquarters of the Barnum and Bailey circus, which occupies extensive grounds in the city proper There are three fine parks, comprising about 250 acres Seaside Park is situated on the sound It has a long and beautiful drive on the sea wall and contains a soldiers' monument and statues of Elias Howe and P T Barnum A fine statue of James P. Beardsley has been erected in Beardsley Park

Bridgeport is an important manufacturing city and has considerable coasting trade, the harbor being safe and accessible for fairly large vessels The principal articles manufactured are sewing machines, corsets, coaches, locomobiles, plush goods, brass, iron, and steel tubing, machinery, cartridges and shells, ordnance, graphophones, compressed-gas capsules, hats, taps and dies, and hardware Some of the factories are of vast size The Union Metallic Cartridge Co has an ammunition park of 425 acres here

The city government is vested in a mayor, elected every two years, a municipal council, and the usual administrative departments, all appointed by the executive, and all, excepting that of public works, where the power is given to a single head, governed by boards The school board, consisting of 12 members, four elected each year for a term of three years, is chosen by popular election The annual expenditures of the city amount to about \$1,700,000, the main items of expense being \$200,000 for the police department, \$222,000 for fire department, \$67,000 for street lighting, \$60,000 for hospitals, asylums, and other charitable institutions, \$50,000 for parks, and \$500,000 for schools Pop, 1890, 48,866, 1900, 70,996, 1910, 102,054, 1913 (est), 113,000

Bridgeport, first settled in 1665, was known as Pequonnock, 1665-94, Fairfield Village, 1694-1701, and Stratfield, 1701-1880 Until incorporated as the Borough of Bridgeport in 1800, it formed part of Fairfield and of Stratford townships In 1836 it became a city, and in 1870 it was enlarged by the addition of a part of Fairfield, and in 1899 of Summerfield and West Stratford Consult Orenti, *A History of the Old Town of Stratford and the City of Bridgeport* (New Haven, 1886), and Waldo, *The Standard's History of Bridgeport* (Bridgeport, 1897)

BRIDGEPORT A village in Belmont Co, Ohio, on the Ohio River opposite Wheeling, W Va, with which it has bridge connection, and on the Pennsylvania and the Baltimore and

Ohio railroads (Map Ohio, J 5) The village is in a coal-mining region, and has glass and sheet and tin mills The government is vested in a mayor and a council Pop, 1900, 3963, 1910, 3974

BRIDGEPORT A borough in Montgomery Co, Pa, 18 miles north of Philadelphia, on the Schuylkill River, on the Philadelphia and Reading Railroad, and on the line of the Schuylkill Navigation Co (Map Pennsylvania, L 7) It has paper, flour, cotton, and woolen mills, steel-works, bikeyards, etc Bridgeport is 6 miles from Valley Forge, and Washington passed through the town with his army on his way to take up winter quarters in 1777 Pop, 1900, 3097, 1910, 3860

BRIDGEER'S PASS An elevated defile in the Rocky Mountains, in southwestern Wyoming, through which the overland stages went before the opening of the Pacific Railroad It is several miles long and in most places has almost perpendicular side walls from 1000 to 2500 feet high

BRIDGES, LAW RELATING TO Legislative authority to erect a bridge is necessary in three cases first, when toll is demanded for its use—the right to take toll being a franchise which cannot be claimed without express grant from the State, second, when the State owns the bed of the stream over which the bridge extends, as is the case in all public or navigable streams, third, when the structure interferes or threatens to interfere with navigation In the last case the authority of our State governments is subject to the power given to Congress by the Federal Constitution to "regulate commerce with foreign nations, and among the several States" (Art I, Sec 8) The States may authorize bridges over navigable streams and may regulate their size, form, and manner of construction Until Congress intervenes in such cases the power of the States is unlimited When it does intervene, however, its will is supreme, and its legislation, within the limits of the constitutional grant, overrides that of any State A bridge constructed over a navigable river in pursuance of an act of Congress is a lawful structure, however much it may interfere with the public right of navigation It is a statutory felony unlawfully and maliciously to pull or throw down or in any way to destroy or do injury to any bridge with intent to make it dangerous or impassable

BRIDGES, ROBERT (1844—) An English poet He was educated at Eton and at Corpus Christi College, Oxford, studied medicine at St Bartholomew's Hospital, London, and held several important hospital appointments before his retirement (1882) Bridges has published eight plays and several volumes of verse, often privately printed His choicest poems (with bibliography) have been reprinted in 3 vols (London, 1898-1901) Late Victorian poetry probably has nothing better than *Prometheus, Eros and Psyche, Achilles in Troy, and Shorter Poems* He is also the author of eight plays of which *Nero* is the best known Bridges has also written on Milton and Keats Especially noteworthy is his *Milton's Prosody* (Oxford, 1893), which has been enlarged and reprinted with an essay by W J Stone on "Classical Metres in English Verse" (Oxford, 1901) His *Poetical Works, Excluding the Eight Dramas*, appeared in 1913, in which year he was appointed Poet Laureate to succeed Alfred Austin

BRIDGES, ROBERT (pen name "Droch") (1858-). An American editor and author. He was born at Shippensburg, Pa., July 13, 1858. After graduating at Princeton he became connected with the New York *Evening Post* and in 1887 was made assistant editor of *Scribner's Magazine*. He is best known for the sprightly reviews which for many years he contributed to *Life* over the signature "Droch." He is also the author of poems and of two prose volumes, *Overheard in Arcady* (1894) and *Suppressed Chapters and Other Bookishness* (1895). His poems were collected in 1902 under the title *Bramble Brae*. In 1904 he wrote *The Roosevelt Book*.

BRIDGES AND DOCKS, MILITARY. The principal types of military bridges for the passage of troops and their supplies are the pontoon or floating, the spar, the trestle, and the suspension bridge. In most cases they must be constructed rapidly, and of such materials as are available, there being usually little time for refined calculations and for procuring the most suitable materials. The sizes of the parts of a military bridge depend primarily, as in other engineering structures, on the loads to be carried. Only in special cases will the width differ much from 8 to 10 feet. This is ample to provide for the passage of infantry in fours, cavalry in column of twos, and guns and wagons fully horsed. It is considered desirable that, in whatever formation the troops may pass, the structure should be made strong enough to sustain them when crowded as a result of some stoppage in that portion of the column which has already crossed. In most cases 100 pounds to the square foot may be taken as the uniform weight for which a bridge intended for the passage of infantry should be made safe. If proportioned for this load, it will also be strong enough for the passage of the various train wagons and of field guns and carriages. If, however, it is to be crossed by steam-traction engines, motor trucks, motor tractors, or other unusually heavy loads, additional precautions may be necessary to enable it to carry them with safety.

In the United States army, where the pontoon bridge was extensively and effectively employed during the Civil War, the bridge material of the Corps of Engineers is included in reserve and advance-guard trains. Where a large army is operating in the field and wide and swiftly flowing rivers are to be crossed the reserve or heavy train must accompany the troops. Such a train is divided into four pontoon divisions and one supply division. Each pontoon division is complete in itself, containing all the material necessary for constructing a bridge 225 feet in length. Each division is divided into four sections—two pontoon and two abutment sections—each pontoon section consisting of three pontoon wagons and one chess wagon. These four wagons contain the material for three bays (or 60 feet) of the bridge. If it is desired to vary the length of a single division, it can be done by diminishing or increasing the number of pontoon sections in the train. The pontoons are flat-bottom boats 31 feet in length, and with a maximum breadth of 5 feet 8 inches, of about 9½ tons' burden, and with sufficient capacity to transfer 40 men fully armed and equipped, besides its crew of pontoniers.

Pontoon bridges may be constructed either by the method of successive pontoons, by rafts, by

parts, or by conversion. The first mentioned is the most usual method. In following it, the pontoons are placed 20 feet apart, at right angles to the axis of a bridge, and anchored upstream and downstream to hold them in position. Five lines of floor beams, known technically as "balks," 5 inches square, rest on the pontoons and are firmly lashed to them. On these floor planks, 1½ inches thick and known as chess, are laid; these are held in position by side rails, lashed through notches in the chess to the balk beneath. The width of the bridge between side rails, when finished, is 10 feet. Bridges of this type received the hardest kind of usage during the Civil War and proved clearly their great value. In the month of February, 1862, a pontoon bridge composed of 60 boats of a reserve train was thrown across the Potomac at Harper's Ferry. The river was then a perfect torrent, the water being 15 feet above the summer level and filled with driftwood and floating ice. Under these unfavorable circumstances the bridge was completed in eight hours, and General Banks's corps, with all its trains and artillery, passed over it without accident or delay.

During the year of 1863 the pontoon train accompanied the army in all its marches through Virginia, frequently bridging the Potomac, Rapidan, and Rappahannock. The headquarters train in 1864 was followed by an advance-guard or light train, which, when a crossing was to be made by surprise, was sent forward with the cavalry to cover the construction of the bridge and hold the position until the main body arrived.

The advance-guard equipment is similar, in general principles, to the reserve. The pontoon, however, instead of being made entirely of wood, is made of canvas held in shape by wooden frames, which can be knocked down for transportation. For transportation purposes the material is so packed that the pontoon wagon contains all the materials for a single bay of 16 feet. The division may therefore be increased or diminished by one or more pontoon wagons, if it is desired to increase or diminish the length of the bridge in units of 16 feet. The width of the bridge is 2 feet less than that of the wooden pontoon bridge. The canvas pontoon, while possessing the advantage over the wooden pontoon of being more easily transported, will of course not stand as hard service. At the same time it has shown its usefulness on many occasions. The pontoon trains with the Army of the Cumberland, in its march from Chattanooga to Atlanta, Savannah, and Washington, in the latter part of the Civil War, were of canvas and gave excellent satisfaction. Where pontoon bridges are constructed at night, with a view to making a passage and surprising the enemy, the floor of the bridge should be covered with straw, in order to reduce the noise of construction to a minimum. Many substitutes for pontoons, such as floating supports, have been devised. Among the more important are rafts made of casks lashed to frames, rafts of timber, and boats of commerce.

European armies have spent considerable effort in attempts to design satisfactory sectional pontoon boats. Instead of using two different types of boat for advance-guard and reserve trains, their general idea is to have boats made of interchangeable sections of which a minimum number shall be joined together in the field to

make a pontoon for their lightest work. When heavier loads must be carried, additional sections are joined to each pontoon, making it of sufficient length, strength, and buoyancy to carry the desired load.

Spar bridges are made with round timber usually cut near the site of the bridge. For narrower spaces of 25 feet or less, the balks consist of single trees stretching across the river. The roadway is made of small saplings smoothed off on top or covered with dirt. For spaces of 30 to 35 feet single lock bridges are usually the most suitable. To construct this type two trapezoidal frames are made of timbers lashed together and braced by diagonal braces lashed to the legs of the frame. These are put in position on the opposite banks, and then lowered so as to rest their tops on each other and form an intermediate support above the middle of the stream for the balk or roadway bearers. For a still wider stream double-lock bridges can be used. In these the frames, instead of resting on each other, rest on cross timbers held apart by straining beams. These cross timbers furnish two intermediate supports over the gap for the balk. For still wider openings the frames are made considerably longer, so that they support each other at a point not less than 10 feet above the roadway. From their junction an additional roadway bearer is suspended by ropes. This, together with the points where the roadway crosses the two frames, gives three points of support.

One of the most generally useful of all the types of bridge is the trestle bridge. Vertical frames are constructed, on which the balks carrying the roadway are placed. In cases where a single trestle is not high enough to come from the bottom of the gap to the desired height of roadway, trestles can be so braced that they will hold others on top of them. This type of bridge particularly lends itself to railroad work, one of the most notable examples of the kind being the bridge across the Potomac Creek, Va., during the Civil War. This bridge was 80 feet high and 400 feet long.

Suspension bridges have not been of general application in the United States military service. The English have made some use of them. They are suitable for wide spans, where it is difficult to secure intermediate supports. An army traveling in a country where its service will probably require the construction of this type of bridge should make provision for carrying along the necessary wire cables, clips, and ropes. A bridge with a span of 100 feet can be constructed with such material, having a roadway 5 feet 8 inches wide in the clear. With a load of infantry in file crowded, the bridge has a stress of about 63,000 pounds in the cables and on the anchorages.

Where time allows or a semi-permanent structure must be provided, almost any of the various types of wood and composite trussed bridges in every-day use may be constructed. Attention has been given by military engineers to modifications of these types to permit of their most rapid construction with boards and other materials most readily carried by troops or most likely to be found en route. Attention has also been given to the design of metal trusses, the parts of which can on some expeditions be carried and erected promptly in the field.

The type of bridge to be used in a given case depends on many circumstances. An army

starting out for extended service in a country such as that covered by many of the operations of the Army of the Potomac in the Civil War—i.e., a rather low, flat country, with many broad streams—would naturally provide itself with pontoon bridges and, having them, would use this type wherever practicable. On the other hand, as the pontoon bridge must be near the surface of the water, it is not well adapted for use in a country where the streams are narrow and the banks so high that trouble would be experienced in the construction of approaches leading to the ends of the bridge. An army expecting to operate in a country provided with poor roads, but fairly well wooded, and having streams not too deep to permit of the establishment of cribs and trestles, might well rely on the trestle-and-spar bridge. If operating in a mountainous country, cut up by gorges and canyons and poorly provided with roads, it should carry the necessary cables, etc., for constructing suspension bridges over gaps too wide for spar bridges. Bridges have been constructed across streams just too deep for fording by running in wagons and laying the balks and roadway on top of them. Railroad bridges can be utilized for the passage of troops on foot and wagons by planking over the ties and sometimes covering with dirt. In many cases no bridge will be needed. In cold weather the ice may be sufficiently thick to permit the crossing of an army. Six inches of good ice will suffice for the passage of the usual loads accompanying an army, 2 inches permits the passage of infantry in single file on planks, 10 to 12 inches bears the heaviest loads of an army. In other cases, as in the famous passage of the Delaware by Washington, the army may be ferried over in boats. Modifications of this method have also been used. Rafts with large deck areas can be made with pontoons by lashing a number of the latter together and flooring them over with chess. On them men and horses can readily be ferried, while rafts of bamboo were used for transporting field artillery across rivers in the Philippines. If there is any current, these rafts are usually supported either by cables attached to anchors set some distance above in the middle of the stream or by cables attached to trolleys running on cables stretched across the stream. A river of shallow depth and moderate current may be forded, where the depth is too great for only short distances, the level of the bottom at these places may be raised temporarily by throwing in brush, logs, and other material. There have also been instances in history of the successful swimming of rivers by small bodies of troops.

Temporary piers or docks are sometimes required to facilitate the landing of troops and material. Such structures are rarely made stronger than to permit small boats, such as launches and lighters, to lie alongside of them and unload. They consist essentially of a top floor and of supports, the relation between the floor and supports being similar to that existing in bridges. The supports are generally either trestles of some type, usually pile-driven, or log cribs sunk with stone. A pierhead may be expedientized by securely anchoring a pontoon raft. When the construction of a pier or dock is not practicable or justified, an aerial cableway is sometimes used for landing field guns and other military material directly from a ship. To operate the cableway, the vessel is anchored and

a cable is stretched from its deck to a tripod extemporized on shore by men who have landed in small boats. A trolley, from which are suspended the various parts to be landed, is drawn along the cable by a rope running to the men stationed on shore.

For a comprehensive technical treatment of the subject of military bridges, consult: *Engineer's Field Manual*, part ii, Bridges, prepared under the direction of the Chief of Engineers, U.S.A. (2d revised ed., Washington, Government Printing Office, 1907); *The Chatham Manual of Military Engineering*, part iii; *Military Bridging and Use of Spars* (London, 1894). An interesting chapter on the "Passage of Rivers" may be found in Fieberger, *A Text-Book of Field Fortification* (New York, 1901).

BRIDGET, SAINT (1303-73) (more properly *Birgit* or *Brigitta*). 1. A Roman Catholic saint. She was born in the palace of Instad, near Upsala, the daughter of a prince of the blood royal of Sweden. In 1316 she married Ulf Gudmarsson, Prince of Nericia, a stripling of 18, by whom she had eight children, the youngest of whom, named Catherine (1336-81), became par excellence the female saint of Sweden. According to the legend, her husband and she made a pilgrimage to the shrine of St. James at Santiago de Compostela, in Spain. This was between 1341 and 1343. On their return they entered the Cistercian Monastery of Alvastra, on the east shore of Lake Vattern, southwest of Stockholm. The picturesque ruins are still standing. There Ulf died in 1344, but without taking monastic vows, and Bridget became a professed nun. From a child she had believed herself to have visions in which Christ appeared to her, and these visions now became more frequent. She felt called upon to found a new order to the homage of the Saviour. This she did in 1346. The first monastery was at Vadstena, on Lake Vattern, only some 10 miles north, on the same side of Alvastra and on her property. It is now a lunatic asylum. They received the rule of St. Augustine, to which St. Bridget herself added a few particulars, but constituted a new order—sometimes called the Order of St. Bridget, sometimes the Order of St. Salvator, or the Holy Saviour—which flourished in Sweden until 1595, when it was suppressed. In 1350 St. Bridget went to Rome, where she founded a hospice for pilgrims and Swedish students, and obtained the papal sanction for her order in 1370, which was reorganized by Leo X. After having made a pilgrimage to Palestine, she died in Rome on her return, July 23, 1373. Her bones were carried to Vadstena, and she herself was canonized in 1391 by Pope Boniface IX. Her festival is on the 8th of October. The *Revelationes Sanctæ Brigittæ*, accounts of her visions, and of the revelations in them, were translated into Latin by her confessors, keenly attacked by the celebrated Gerson, but obtained the approval of the Council of Basel and passed through many editions. Besides the *Revelations* there have been attributed to this saint a sermon on the Virgin, and five discourses on the passion of Jesus Christ, preceded by an introduction which was condemned by the congregation of the *Index*. For her autobiography and the history of the order, consult: *Scriptores Rerum Societarum Mediæ Aevi*, vol. iii (Stockholm, 1871-76); Eng. trans. of her *Revelations* (London, 1873); also the biographies by G. Binder (Munich, 1891), V. F. de Flavigny (Paris, 1892), and

F. J. Partridge (New York, 1888), of which the first treats also of her order. See BRIGITTINES.

2. Not to be confounded with this Swedish saint is another St. Bridget, St. Brigid, or St. Bride, as she is more commonly called—a native of Ireland, born at Faughart, 47 miles north of Dublin, 453—the child of a man of royal race and his bond servant. She was brought up by a wizard, who had bought her mother and whom she converted to Christianity, but was liberated by the king. She became a nun and founded the church and monastery of Kildare (the church of the Oak) and there died Feb. 1, 523. She was unquestionably a woman of rare ability and consecration and properly became, along with Patrick and Columba, one of the three great saints of Ireland. Her story, as told in Irish legends, is very attractive and based probably on facts. It is found in Whitley Stokes, *Three Middle-Irish Homilies on the Lives of Saints Patrick, Brigit, and Columba* (Calcutta, 1877). She was renowned for her beauty. To escape the temptations to which this dangerous gift exposed her, as well as the offers of marriage with which she was annoyed, she prayed God to make her ugly. Her prayer was granted, and she retired from the world, founded the monastery already mentioned, and devoted herself to the education of young girls. Her day falls on the 1st of February. She was held in great reverence both in England and Scotland and was regarded by the Douglasses as their tutelary saint. Consult: Knowles, *Life of St. Brigid* (New York, 1907); Westman, *Brigitta-studier* (Upsala, 1911); Wilkie, *St. Bride* (Boston, 1912).

BRIDGETON, brĭj'ton. A city, port of entry, and the county seat of Cumberland Co., N. J., 38 miles southeast of Philadelphia, at the head of navigation on the Cohane River, and on the New Jersey Central and the West Jersey and Seashore railroads (Map: New Jersey, B 5). Among its noteworthy features are the public library, Ivy Hall Seminary, city hospital, county hospital, and insane asylum, and fine county and government buildings. Bridgeton has good transportation facilities, and the surrounding region is exceedingly fertile and well cultivated. The manufactures of the city include glass, gas pipes, castings, machinery, hosiery, candy, shirts and shirtrwaists, dresses, carriages and wagons, boilers, lumber, and flour, and the canning of fruits and vegetables is carried on. Though settled long before the Revolution, Bridgeton was not incorporated until 1865. It was made a port of entry in 1790. The city has adopted a modified form of commission government. The water works are owned and operated by the municipality. Pop., 1890, 11,424; 1900, 13,913; 1910, 14,209. Consult Nichols, *The City of Bridgeton*, New Jersey (Philadelphia, 1889).

BRIDGE-TOWN. The capital of the British West Indian island of Barbados, situated on the west coast, along the northeast shore of Carlisle Bay (Map: West Indies, H 4). The town is the seat of Codrington College and of the Bishop of Barbados, and among its prominent structures are the government buildings, the town hall, hospital, and the buildings of the garrison. Its trade, valued at \$5,000,000 annually, consists of sugar, molasses, alous, and mineral oil, and it is the terminus of the only railroad on the island. Bridgetown was founded in the first half of the seventeenth century and for some time was known as Indian Bridge. It has

suffered severely from fires, notably in 1666, 1766, and 1845, and in 1831 it was visited by a disastrous hurricane Pop, 1911, 16,648

BRIDGEWATER A port of Lunenburg Co., Nova Scotia, at the head of the La Have estuary, 80 miles west of Halifax (Map Nova Scotia, E 4) Lumber constitutes its chief industry, and it contains the main offices and workshops of the Halifax and Southwestern Railway The neighborhood is resorted to for its excellent trout and salmon fishing The United States is represented by a consular agent The town has shipyards, planing, shingle, and carding mills, foundries and tanneries, wagon factories, granite and marble works, etc., and forest products are exported Bridgewater suffered from a destructive fire in 1899 Pop, 1901, 2293, 1911, 2775

BRIDGEWATER A town in Plymouth Co., Mass., 27 miles south of Boston, on the New York, New Haven and Hartford Railroad (Map Massachusetts, F 4) The town has a public library, and is the seat of a State normal school and of a State farm It contains iron works, a foundry, a tack factory, shoe factories, brickyards, and a cotton-gin factory The government is administered by town meetings, held annually Pop, 1900, 5806, 1910, 7688 Settled in 1645 as a plantation of Duxbury, Bridgewater was incorporated as a separate township in 1656, when its old name, Nunkatasset, was discarded It was one of the first towns to be settled in the interior of Massachusetts It included the territory of the towns later incorporated as East, West, and North Bridgewater (now Brockton) Consult Mitchell, *History of Bridgewater* (Bridgewater, 1897)

BRIDGEWATER, FRANCIS EGERTON, third and last DUKE OF (1730-1803) An English canal builder, sometimes called the "Father of British Inland Navigation" He was the youngest son of Scioop, fourth Earl and first Duke of Bridgewater, and succeeded his elder brother, second Duke, in 1748 In 1760 he obtained an Act of Parliament for making a navigable canal from Worsley to Salford, Lancashire, and carrying it over the Mersey and Irwell at Barton by an aqueduct 39 feet above the surface of the water, and 200 yards long, thus forming a communication between his coal mines at Worsley and Manchester on one level In this and his later great undertakings he was aided by the skill of James Brindley (q v), the celebrated engineer, and expended large sums of money He was also a liberal promoter of the Grand Trunk Navigation, and the impulse he thus gave to the internal navigation of England led to the extension of the canal system throughout the kingdom

BRIDGEWATER, FRANCIS HENRY EGERTON, eighth EARL OF (1750-1820) The son of John Egerton, Bishop of Durham, and grandnephew of the first Duke of Bridgewater. He was born in London, Nov. 11, 1750, and succeeded his brother as Earl in 1823 He was educated at Oxford, becoming fellow of All Souls College, 1780 The same year he became prebendary of Durham, in 1781 rector of Middle, and in 1797 of Whitelchurch, both in Shropshire, and he held these preferments till his death He was prince of the Holy Roman Empire He was very eccentric, for his home in Paris, where he lived the latter part of his life, was filled with cats and dogs, some dressed up as men and women, and he drove them out in his carriage and fed them

at his table When he died unmarried, in Paris, Feb. 11, 1829, the title became extinct By his last will, dated Feb. 25, 1825, he left £8000, invested in the public funds, to be paid to the author of the best treatise "*On the Power, Wisdom, and Goodness of God as Manifested in the Creation*," illustrating such work by all reasonable arguments as, for instance, the variety and formation of God's creatures, in the animal, vegetable, and mineral kingdoms, the effect of digestion and thereby of conversion, the construction of the hand of man and an infinite variety of other arguments, and also by discoveries, ancient and modern, in arts, sciences, and the whole extent of modern literature" The then president of the Royal Society of London, Davies Gilbert, to whom the selection of the author was left, with the advice of the Archbishop of Canterbury, the Bishop of London, and a noble friend of the deceased Earl, judiciously resolved that, instead of being given to one man for one work, the money should be allotted to eight different persons for eight separate treatises, though all connected with the same primary theme (See **BRIDGEWATER TREATISES**) He wrote himself a number of books, biographical, historical, and scientific He left his manuscripts, relating mostly to French and Italian history and literature, to the British Museum, with 112,000 to keep up the collection

BRIDGEWATER TREATISES Eight celebrated works *On the Power, Wisdom, and Goodness of God*, by eight of the most eminent authors in their respective departments, published under a bequest of the eighth Earl of Bridgewater (q v), whereby each received £1000 with the copyright of his own treatise They are Thomas Chalmers, *The Adaptation of External Nature to the Moral and Intellectual Constitution of Man* (London, 1833), William Prout, *Chemistry, Meteorology, and the Function of Digestion Considered with Reference to Natural Theology* (London, 1834), William Kirby, *History, Habits, and Instincts of Animals* (London, 1835), Buckland, *Geology and Mineralogy Considered with Reference to Natural Theology* (London, 1837), Charles Bell, *The Hand Its Mechanism and Vital Endowments as Evincing Design* (London, 1837), John Kidd, *Adaptation of External Nature to Physical Condition of Man* (London, 1837), William Whewell, *Astronomy and General Physics Considered with Reference to Natural Theology* (London, 1839), Peter Mark Roget, *Animal and Vegetable Physiology Considered with Reference to Natural Theology* (London, 1840)

BRIDGMAN, BELJAH COLEMAN (1801-61) An American missionary to China He was born in Massachusetts, was a graduate of Amherst (1826) and of Andover (1829) He went as missionary to China in the year last named and joined Dr. Morrison at Canton Having learned to speak and write the Chinese language, he acted as official interpreter for the Imperial Commissioner Lin (1839), and afterward as interpreter and secretary to the United States Minister, Caleb Cushing (1844) *The Chinese Repository*, a valuable magazine, was founded by him In 1847 he established a mission station at Shanghai, where his version of the Bible was printed His Chinese *Chrestomathy*, in the Canton dialect, a quarto of 734 pages, printed and contributed to by S. Wells Williams, was the first practical manual of the Cantonese

dialect prepared in China. He died in 1861 at Shanghai, in the fullness of his powers. His life has been described by his widow, Mrs. E. J. G. Bridgman, under the title *The Pioneer of American Missions in China* (New York, 1864).

BRIDGMAN, FREDERIC ARTHUR (1847-). An American genre and historical painter. He was born at Tuskegee, Ala., Nov. 10, 1847. From 1863 to 1866 he was a steel engraver for the American Bank Note Company. In the latter year he went to Paris, where he studied in the Ecole des Beaux-Arts under Gérôme. His earliest paintings were Breton and Norman subjects, like the well-known "American Circus in Normandy," in which characteristic American types in the performers were in interesting contrast to the French peasants who filled the seats; and "Two Gulls in a Canoe." A voyage to Algiers in 1871 caused a change in his subjects, which were henceforth Oriental, studied in extensive travels in northern Africa, Egypt, and Nubia. His later work, though sometimes deficient in line, is characterized by brilliancy of color and facility of execution. Although residing in Paris, he exhibits frequently in the United States, and was elected to the National Academy in 1891. In 1900 he was chairman of the department of American Art in the Paris Exposition. He is a officer of the Legion of Honor (1907) and of the Bavarian Order of St. Michael and has received several medals. Among his principal works are: "The Diligence" (Liverpool Gallery); "The Procession of Apis" (James Gordon Bennett); "The Burial of a Mummy," which received a medal at the Paris Exposition of 1878; "The Destruction of Pharaoh's Host" (1892), in the Academy of Arts, St. Petersburg, which possesses two other works by him; "Ars Dramatis"; "Procession in Honor of Isis"; "The Bocher, Biskra" and the "Greek Girl." He is a composer of orchestral music, has written symphonies, and is the author of several works on art subjects in English and French.

BRIDGMAN, HERBERT LAWRENCE (1844-). An American journalist and Arctic explorer. He was born at Amherst, Mass., graduated in 1866 at Amherst College, entered journalism, and became associate editor of the Brooklyn (N. Y.) *Standard-Union*. He accompanied and was historian of the Peary auxiliary expedition in 1894; in 1897 assisted Professor Libbey of Princeton University in scaling the Mesa Encantada ('Enchanted Mesa') of New Mexico; commanded the Peary auxiliary expeditions of 1899 and 1901; and was a delegate to the International Polar Commission at Brussels in 1908. He is the author of *The Sudan-Africa from Sea to Centre* (1905).

BRIDGMAN, LAURA DEWEY (1829-89). A blind deaf-mute, born in Hanover, N. H., Dec. 21, 1829. As the result of a fever, at the age of two, she lost sight, smell, and hearing. When she was eight years old, Dr. Howe, of Boston, undertook her education, and succeeded in teaching her to read and write well, and to think clearly, so that she was later employed in teaching. Consult Lampton, *Life and Education of Laura Dewey Bridgman* (Boston, 1878); Mrs. Elliott and Hall, *Laura Bridgman* (Boston, 1903).

BRIDGE/NORTH (for *Brugge Morfe*, the bridge of the wood Morfe, on the opposite bank of the Severn). A town of Shropshire, England, on both sides of the Severn, 20 miles southeast

of Shrewsbury (Map: England, D 4). It consists of an upper and a lower town connected by a bridge over the Severn. A tower, all that remains of the ancient Norman castle, stands on a rock 60 feet above the river. There are two churches, and a town hall dating from 1652. The town owns its water and gas works and maintains markets and a cemetery. It has an ancient Latin school, a mechanics' school, and a public library. Its industries include the manufacture of carpets and woolen goods. The house in which Thomas Percy, author of the *Reliques*, was born, and which was built in 1580, is still standing. Pop., 1891, 5865, 1901, 6049; 1911, 5708. The town, which was at one time called *Bruges* or *Brug*, is said to be of Saxon origin. In the beginning of the twelfth century Robert de Belesme defended the town unsuccessfully against Henry I. It was besieged in the same century by Henry II, and during the Civil War it was burned by the parliamentary forces.

BRIDGTON. A town in Cumberland Co., Me., 38 miles northwest of Portland, on the Bridgton and Saco River and the Maine Central railroads (Map: Maine, B 4). Situated in the White Mountains and almost surrounded by lakes, the town is a popular summer resort. It contains Bridgton Academy (incorporated 1808), a public library, and a woolen goods factory. Pop., 1900, 2868; 1910, 2960. Bridgton was settled in 1770 by Capt. Benjamin Kimball and was formerly known as Pondicherry.

BRIDGE/WATER (from *Burgh-Walter*, the town of Walter Douay, its founder). A town and port of Somersetshire, England, on the Parret, 12 miles by river from the Bristol Channel and 30 miles southwest of Bristol (Map: England, D 5). The town is chiefly built of brick. The Parret admits vessels of 700 tons up to the town; it rises 36 feet at springtides and is subject to a tidal bore often detrimental to shipping, but the town has considerable coastwise trade. The town owns its water supply and maintains public libraries and baths. Bath or scouring bricks, peculiar to Bridgewater, are made here of a mixture of sand and clay found in the river. There are also factories for the manufacture of iron and copper ware. Admiral Blake was a native of Bridgewater. Pop., 1891, 13,264; 1901, 15,209; 1911, 16,802. The town received its first charter from King John in 1201. It suffered severely in the Civil War, when it was taken in turn by both Royalists and Roundheads. Sedgemoor, the scene of the defeat of the Duke of Monmouth by the royal forces in 1685, lies a little to the southeast of the town.

BRIDLE (from its similarity to the bridle of a horse). A chain or rope span, the ends being made fast and the power or weight between, the bowlines are attached to the sails in this way. The chains of permanent moorings, if the ends are attached to separate anchors, form a *mooring bridle*, the vessel being made fast to the centre of the span.

BRIDLE AND BIT. See **SADDLERY**.

BRIDLINGTON, local pron. burlington, or BURLINGTON. A seacoast town in the East Riding of Yorkshire, England, 6 miles west of Flamborough Head, 40 miles east-northeast of York (Map: England, F 2). Bridlington is situated on a gentle slope in a recess of a beautiful bay. It has the aspect of an old town with narrow, irregular streets. Bridlington is well known as a watering place. It has an excellent

harbor, carries on a considerable trade in grain, and possesses an intermittent spring which supplies the town with fresh water. The town was incorporated in 1899. It has several schools and a library. Pop., 1891, 8919, 1901, 12,473, 1911, 14,334. Bridlington is noted for its chalk-flint fossils. Remains of Danish and Saxon times are found around Bridlington. After the Conquest it became the site of a rich Augustine abbey, traces of which still exist in the parish church of St Mary. Consult Thompson, *Historical Sketches of Bridlington* (Bridlington, 1821).

BRIDFORD A seaport town of Dorsetshire, England, at the confluence of the Asker and Brit, 2 miles from the English Channel and 16 miles west-northwest of Dorchester (Map, England, D 6). Its public buildings include the fine parish church of St Mary, of the Perpendicular period, a town hall, markets, mechanics' institute, and school of art. It has manufactures of ropes, cordage, sailcloth, etc., and carries on some foreign and coasting trade. Bridport mint is mentioned in the *Domesday Book*. From Henry VIII it received a monopoly of the cordage supply for the British navy. Pop., 1891, 6611, 1901, 5962, 1911, 5919.

BRIE, brē An ancient district of France situated between the rivers Seine and Maine, now comprised in the departments of Aisne, Marne, and Seine-et-Marne. Its capital was Meaux. In olden times it was almost wholly covered by a forest. Subdued by the Franks, it formed, successively, part of the Kingdom of Neustria and of the provinces of Champagne and Île-de-France. It was ruled by its own counts until it became crown property in 1361. Brie was, and is still, celebrated for its grain and dairy products, especially cheese.

BRIEF (OF, from Lat. *brevis*, brief) In the ancient law writers, a writ or breve. Now, a concise and orderly statement of the points of law, pleadings, and evidence to be laid by one party to a cause before a court at its trial. The word is used in England and in the United States with very different meanings. In Great Britain it is the duty of the attorney or solicitor to prepare the case only—to draw up and serve papers, to marshal the evidence, to prepare the case for trial generally, and to the barrister is committed the task of arguing the case before the court, introducing the evidence, cross-examining, and taking entire conduct of the case in open court. A brief, under this English practice, is the concise statement of the case as it leaves the hands of the attorney, and it serves as a guide to the barrister and as his instructions for proceeding in open court. As soon as a counsel is briefed he has authority to act as his client's representative in all matters involved in the litigation. (See **BARISTER**.)

In the practice of courts in the United States, one person serves the office of both the English attorney and barrister. In our courts, accordingly, the brief is the abbreviated statement of pleadings, affidavits, evidence, and all points of law to be argued, prepared by the counsel for his own use, or to lay before the court as an assistance in following his presentation of the case. In appellate courts of the States, and in the United States courts, the brief is the skeleton or analysis of the argument prepared by the counsel, setting forth the legal propositions he offers, citing cases in support thereof, and indicating the rulings for which he argues. It is

usual that such a brief should be printed and furnished to the court, to the official reporter, and to the opposing counsel. Consult authorities referred to under **PRACTICE** and N. Abbott, *Brief Making and the Use of Law Books* (St. Paul, 1906).

The phrase *Brief of Title* is sometimes employed in place of the usual term *Abstract of Title* (q.v.), to denote the concise statement of the deeds, conveyances, and changes in ownership which may have occurred in the history of the title to a certain piece of real estate.

BRIEF, PAPAL (Lat. *brevis*, short, of Ger. *Brief*, a letter). A word used to denote certain letters of the Popes, which, however, do not receive their name from the brevity of the composition, but from the smallness of the calligraphy. The papal brief differs from the papal bull (q.v.) in several points. It gives decisions on matters of inferior importance, such as discipline, dispensations, release from vows, indulgences, etc., which do not necessarily require the deliberations of a conclave of cardinals. Still, it is not to be confounded with *motu proprio*, or private epistle of the Pope as an individual, as its contents are always of an official character, though expressing a kind of familiar parental authority, and the brief is consequently superscribed *Papa*, while the form of address is *dilecte fili* ('beloved son'). It is signed not by the Pope, but by the *segregario de brev*, an officer of the papal chancery, with red wax, and only with the Pope's private seal, the fisherman's ring. Hence it concludes with the words *Datum Romæ sub annulo piscatoris* ('given at Rome under the ring of the fisherman').

BRIEG, brĕk (Slav *Brĕgŭ*, bank) A town of Silesia, Prussia, situated on the left bank of the Oder, about 27 miles southeast of Breslau, on the railway line between Breslau and Vienna (Map, Prussia, G 3). It was formerly surrounded by ramparts, which have been converted into promenades. The town has a number of manufactories and produces principally machines, textiles, cigars, and sugar. It has a cattle market of some importance. Pop., 1900, 24,114, 1905, 27,486, 1910, 29,035. Consult Schönborn, *Geschichte der Stadt und des Fürstentums Brieg* (Brieg, 1907).

BRIEGER, brĕ'gĕr, JOHANN FRIEDRICH THEODOR (1842-) A German Protestant historian. He was born at Greifswald, June 4, 1842, studied there and at Erlangen and Tübingen, became professor of Church history at Marburg (1873) and at Leipzig (1886). He edits the *Zeitschrift für Kirchengeschichte* (Gotha) and has written principally upon the German Reformation. Among his works are *Quellen und Forschungen zur Geschichte der Reformation* (1884), *Die theologischen Promotionen auf der Universität Leipzig 1428-1559* (1894).

BRIEGLER, brĕ'glĕr, HANS KARL (1805-79) A German jurist, born in Bayreuth. He was professor of law at Erlangen in 1842, and at Göttingen in 1845. He achieved distinction by establishing an historical basis for the theory of civil procedure. His investigations into the mediæval literature on this subject are also important. In addition to his principal work, *Ueber caelutatorische Urkunden und Ehelutprozess* (1839), he wrote *Summarium Cognoscere, Quid et Quale Fuerit apud Romanos* (1843), *Rechtsfälle zum akademischen Gebrauch* (1848-50), *Einleitung in die Theorie der sum-*

marischen Prozesse (1859); *Vermischte Abhandlungen* (1868).

BRIEL, brél, or **BRIELLE**, brâ-êl', or **THE BRILL**. A fortified seaport town on the north side of the island of Vorne, in the province of South Holland, Netherlands (Map: Netherlands, C 3). It is situated near the mouth of the Meuse, about 14 miles west of Rotterdam. Briel possesses a good harbor and is intersected by several canals. The large St. Catherine's Church contains the beautiful tomb of Admiral Philip-pus van Almonde. The town has some trade. Pop., 1900, 4107; 1911, 3810. The seizure of Briel by the "Beggars of the Sea," under William de la Marck, April, 1572, opened the long struggle for independence waged by the Netherlands against Philip of Spain.

BRIENNE-LE-CHÂTEAU, brê-ên' le sha'tô' (Fr. Castle Brienne, anciently, Lat. *Brienna*, capital of the *Bramovices*), or **BRIENNE-NAPOLEON**, -na'pô'le-ôn'. A small town in the department of Aube, France, on the right bank of the river Aube, about 14 miles northwest of Bar-sur-Aube. It is celebrated as the place where Napoleon I received his earliest military education, entering the military school here in 1779, when he was 10 years old, and remaining until 1784. On Jan. 20, 1814, Brienne-le-Château was the scene of a bloody and indecisive battle between the armies of Napoleon and Blücher. Consult Jaquot, *Notice historique sur Brienne* (Paris, 1832).

BRIENZ, brê-ên's'. A town of the canton of Bern, Switzerland, beautifully situated at the foot of the Bernese Alps, on the northeast shore of the lake of the same name, and about 30 miles east-southeast of Bern (Map: Switzerland, C 2). The town is the centre of the Oberland wood-carving industry, and its cheese is held in high repute. Pop., 1900, 2600; 1910, 2518.

BRIENZ LAKE or **A**. A valley lake in Switzerland, visited by many tourists. It is 1850 feet above sea level, is about 8 miles long and 2 miles broad, is formed by the river Aar, at the foot of the Hasli valley, and, through the same river, discharges its waters into Lake Thun (Map: Switzerland, B 2). Its average depth, which is said to be in some places 900 feet, is about 500 feet. It is surrounded by elevated mountains, the principal one being the Rothorn, from which splendid views of the whole range of the Bernese Alps are obtained. A small steamer plies daily on the lake between Brienz and Interlaken, touching at the celebrated Giessbach Fall on every trip.

BRIER CREEK. A stream in Warren Co., Ga., at whose junction with the Savannah a force of about 1500 Americans (mostly militia), under General Ashe, was defeated by a somewhat larger British force, under General Prevost, on March 3, 1779. Of the British, only 5 were killed and 11 wounded; while of the Americans 200 were killed or wounded, 200 were taken prisoners, and only about 450 reached the main army, the rest having retired to their homes. The victory restored Augusta to the British, and reinstated temporarily the royal government of Georgia.

BRIERLEY, BENJAMIN (1825-96). An English writer, born at Failsworth, Lancashire. After meagre schooling he became a Manchester weaver, but read extensively in the English poets. It was after 1855 that he began to be known for his stories and verses of Lancashire, written, many in dialect, under the pseudonym

of "Ab-o'-th'-Yate," and very accurate in point of local color. These include: *A Summer Day in Daisy Nook* (1859); *Tales and Sketches of Lancashire Life* (1863); *The Laycock of Langley Side* (1864); *Irkdale* (1865). *Ab-o'-th'-Yate in Yankee Land* (1887). He edited *Ben Brierley's Journal* (1869-91). A collected edition of his works appeared in 1882-86.

BRIERLEY HILL (*brier ley, lea*, field). A town of Staffordshire, England, 2 miles north-northeast of Stourbridge, on the Stour (Map: England, D 4). Large quantities of coal, iron, and fire clay are found in the neighborhood, and its principal industries are connected with coal mines, iron foundries, glass and pottery works, and brick kilns. Pop., 1891, 11,831; 1901, 12,040; 1911, 12,263.

BRIERLY, BOB. The principal character in Tom Taylor's play *The Ticket-of-Leave Man*.

BRIERRE DE BOISMONT, brê'râ' de bwis'môn', ALEXANDRE JACQUES FRANÇOIS (1788-1831). A French physician and authority on insanity, born in Rouen. He took his degree in medicine in 1825, in which year he published his first work, *Éléments de botanique*. In 1831 he spent some months in Poland, studying the cholera, and upon his return published the results of his investigations in a treatise, which obtained for him a gold medal from the Institute. He then turned his attention to mental diseases, founding and maintaining an asylum for the treatment of the insane. His principal works are: *La pellagre et la folie pellagreuse* (1834); *La menstruation* (1842); *Le délire aigu* (1844); *Les hallucinations* (1845); *Le suicide* (1854).

BRIEUX, brê'x', EUGÈNE (1858-). A French dramatist, born in Paris of poor parents. He began his career as a journalist, but at the age of 21 collaborated with Gaston Salandri in the production of a one-act play entitled *Bernard Pataway*. He did not, however, begin writing seriously for the stage till 11 years later, when he made his first success in *Ménage d'artistes* at the Théâtre Libre (1890). After this he became one of the most prolific of French dramatists. He was elected to the Academy in 1909. His work is distinguished by seriousness of purpose and deep insight into the social conditions of his time. His plays, almost without exception, deal with definite social problems of the day. *Blanchette* (1892) is an arraignment of the system of public education in its application to girls of the working class; *M. de Réboral* (1892) is a satire on pharisaism; *L'Engrenage* (1894) shows the overwhelming temptations that a public official is subjected to under the French political system; and *Les bienfaiteurs* (1896) is a scathing denunciation of the insincerity and frivolity of fashionable charity. By *L'Évasion* (1896) is exposed the fallacy of indiscriminate belief in the scientific doctrine of heredity and by *Les trois filles de M. Dupont* the miseries that French law and custom impose on poor girls of the middle class. *Le berceau* (1899) is a plea for the indissolubility of the marriage bond after a child has been born; *Le résultat des courses* (1898) shows the evil results of betting among workmen; while *La robe rouge* (1901), crowned by the Academy, exposes the injustice of the law. In *Les remplaçants* (1901) Brieux attacks the practice of putting children out to nurse; in *Les aravies* (1901) he paints the horrors of venereal disease; and in *Petite amie* (1902) he

portrays the life of a Parisian shop girl *Mateuette* (1903) is an arraignment of society for its attitude toward women who become mothers outside of marriage. In his later plays—*Les hennetons* (1906), *La française* (1907), *Simone* (1908), *Suzette* (1910), *La foi* (1912), *La femme seule* (1912)—he shows more lightness and a greater desire for artistic expression, but even in these he is obviously the social reformer rather than a literary artist. A translation of *Les amants* was produced in New York in 1913 with notable success. Consult *Three Plays by Brieux*, with a preface by Bernard Shaw (New York, 1911).

BRIG and BRIGANTINE (Fr. *brigantin*, It. *brigantino*, from *brigante*, pirate. *Brig* is the shortened form, just as *cab*, from *cabriolet*). A *brig* is a square-rigged vessel with two masts. An *hermaphrodite brig* is a two-masted vessel, with the mainmast of a schooner and the foremast of a brig. A brig's mainsail is the lowest square sail on the mainmast, whereas the mainsail of a brigantine is a fore-and-aft sail like that of a schooner. Aside from its mainsail a brigantine is like a brig.

BRIG A town in the canton of Valais, Switzerland, on the Rhône, 17 miles east of Leuk (Map Switzerland, C 2). It is situated at the foot of the Simplon Pass, 1½ miles above the north end of the Simplon Tunnel, and commands a view of magnificent mountain scenery. It has an ancient Jesuit monastery, and the sixteenth-century Stockhalpe Castle, the master of which controlled and protected the trade over the Simplon. Pop. 1900, 2198, 1910, 2699.

BRIGADE (Fr. It. *brigata*, company, from *brigare*, to strive, *briga*, strife). A number of regiments, battalions, or corps of any arm of the service combined in one group and under one general command. The system of grouping battalions and regiments into brigades was first introduced by the great generals of France in the reign of Louis XIV (1642-1715)—Turenne, Condé, and others, and in England by Marlborough. The idea was soon imitated by every army in Europe, the rule generally being to group together regiments of infantry of two or three battalions, each battalion 500 or 600 strong, and regiments of cavalry of four squadrons, each having a strength of from 100 to 150. Artillery was not as yet prepared for this form of organization, as most of the guns were attached to the regiments. The organization of the army as a whole is the factor which determines the character and strength of component parts in times of peace, alterations made in the field are usually to facilitate command, to insure greater mobility and better adaptation to the circumstances with which the army as a whole is confronted. In the United States a brigade may consist of either infantry, cavalry, or artillery, or, in the case of a reinforced brigade, of a combination of all three arms, under the command of a brigadier general. There are usually three regiments in a brigade, though the number may be greater or less. In England the strength of a brigade varies with the circumstances under which it is formed. It has no arbitrary strength or place in the organization of the army. In continental European armies two regiments is the average strength in time of peace. See **ARMY ORGANIZATION**.

BRIGADE MAJOR The adjutant of a brigade commander. The title is not employed in the United States army. See **ADJUTANT**.

BRIGADIER GENERAL (Fr. from *brigade*). In the United States army, the rank appropriate to the officer commanding a brigade (qv). The rank is intermediate between that of colonel and major general. In the English and European armies generally, the brigade commander is usually a colonel or lieutenant colonel, who for a brief period or for some particular service, and largely because of his seniority, is placed upon brigade duties. The brigade almost invariably contains the brigadier general's own regiment. See **RANK AND COMMAND**.

BRIG'ANDAGE (Fr. OF *brigand*, a foot soldier, brigand, from It. *briga*, strife). The system of robbery practiced by armed men, or bands of armed men, on the highways, in the mountains, or in waste places. At the dawn of history violence was the natural stage, and since the beginning of civilization brigandage has prevailed wherever natural, political, and economic conditions have united to make peaceful pursuits difficult and unremunerative, and plunder profitable. Given a country of mountains, desert, or marshes, a poverty-stricken peasantry oppressed by alien masters, a period of civil war and anarchy, and brigandage is sure to spring up. Countries like Arabia, where man has in great part remained in a state of nature, are still the homes of bands, or even clans and entire nations of robbers. In Ancient Greece highway robbery flourished as a survival of prehistoric times. One of Theseus's great labors was clearing the Corinthian Isthmus of the brigands that infested it. In distinction from his forefathers, the modern Greek bandit is the product of just such conditions as have been pronounced favorable to the growth of outlawry. Greece before 1827 presented the spectacle of a country impoverished by the anarchic rule of the Turk. The mountains and ravines of Hellas became the home of the Greek *Klephs*, who were raised above the common level of brigands by the national spirit which at times animated them, elevating them to the rank of heroes. The names of Marco Bozzaris and Colocotronis, and other leaders of the *Klephs*, are well known in connection with the Greek War of Liberation.

Rome was founded by outlaws, and during the social and civil wars the Italian Peninsula was a stamping ground for bands of renegade soldiers, runaway slaves, and gladiators, who were often bold enough to enter the suburbs and towns, plundering tombs and deserted houses, kidnapping and assassinating for pay. The spurs of the Apennines and the marshes of the Campagna afforded them safe retreats and admirable centres of operation. The splendid military roads of Rome were not safe from them.

Britain had her Hereward (c1060) and her Robin Hood (c1170), with his Merry Men of Sherwood, the last champions of Saxon England against the Norman. The clearing of the forests, the draining of the fens, the repression of the lawless barons by the crown, made systematic brigandage impossible. Though it flourished in Scotland, in Wales, and on the border, the craft died out in England. Jack Sheppard (1702-24) and Dick Turpin (died 1730) are brilliant but solitary phenomena. France, likewise, was too firmly governed after 1600 to suffer the existence of powerful robbers, though the country had been devastated by them during the Hundred Years' War and the Civil wars. Still, France may boast of two great

names in modern times: Cartouche (1693-1721), who terrorized Paris for a long period, and Mandrin (1724-55), whose sphere of operations lay south of the Loire and chiefly in Languedoc. The robber barons of Germany are historic. They swarmed in the southwestern part of the country, on the Rhine, and in what is now Bavaria, Württemberg, and Baden. The great cities of southern Germany, Nuremberg, and Augsburg especially, suffered greatly from their depredations and carried on feuds with them. Maximilian I (died 1519) did much to crush out these predatory knights by putting them under the ban and proclaiming a general peace for the Empire. They disappeared before the power of the consolidated principalities after the Thirty Years' War. About the time of the French Revolution Johann Buckler, apprenticed to a hangman, ran away and set up for himself as brigand, in the Rhine Provinces. "Schunderhannes," as he was generally called, was absolutely fearless and frequently captured bands of travelers single-handed, though he commanded more than 100 men. He was executed at Metz in 1803. Spain has always been a land of outlaws. The system of imposing extravagant imposts on foreign and domestic trade, which has always been followed, made smuggling immensely profitable, and the country was consequently filled with bands of contrabandists, who plundered and murdered when they could not smuggle. From 1808 to 1876, moreover, Spain was at various times the scene of guerrilla warfare; the nation against Napoleon, Liberals against Absolutists, and Cristinos against Carlists. In such stormy times freebooters naturally thrive. The most famous of Spanish outlaws is probably Don José María, best known, no doubt, as the hero of Prosper Mérimée's *Carmen*.

Italy, in modern times, has been the stronghold of brigandage, because the conditions necessary for the existence of brigandage have prevailed there in the most developed form. During 400 years the country served as a toy for European nations and was repeatedly torn up and patched together to suit the designs of European diplomacy. In southern Italy especially, the people were reduced to misery, deprived of all semblance of wise and stable government, and subjected to foreign masters. Naples was a flourishing country in the sixteenth century when Spain took possession of it. Spanish tyranny and maladministration crippled the country's resources, stifled its political life, and drove its bold and active spirits to the mountains. The period of the French Revolution was the golden age of brigandage, when Italy supplied the world with its most daring criminals, and operative compositors with picturesque subjects for their librettos. Then rose Fra Diavolo (q.v.), bandit and monk, hanged in 1806 by the French, against whom he maintained the cause of the Bourbons; Peter of Calabria (c.1810), who proclaimed himself "Emperor of the mountains, King of the forests, Protector of the highways"; the priest, Cirro Annochiarso, who said to the Father who came to give him absolution before his execution for numerous bloody crimes, "No tomfoolery. We are both in the business"; Marco Sciavo; Crocco; and many others. The Bourbon uprising in 1860 filled southern Italy with armed bands of partisans, who degenerated into banditti and were stamped out only after hard campaigning. The peninsula of Italy is at present almost cleansed of the pest, but in Sicily

it rages as violently as ever. The Sicilian outlaws hold the country in subjugation and live in open alliance with the peasantry and the officials. In Sicily, too, the evil of secret societies is prominent, the Mafia finding its home there. The Mafia dates back to the time of the Norman invaders, when the enslaved people were ruled by the foreign barons, who neither granted them justice nor afforded them protection. A state of things which made possible a murderous uprising like the Sicilian Vespers (q.v.) brought about the formation of secret societies among the peasants, organized for their mutual protection. Knowing what justice they were likely to obtain in the lord's court, they pledged themselves never to appeal to the authorities, but to leave all causes to be decided by the society. Continued misgovernment confirmed the peasant in his views, and to the present day he regards all authority and the machinery of government with distrust, and looks upon the Mafia as a national institution, and upon the brigands as victims of oppression. The fact that the society has lost its original character, and that the brigands are mere criminals, does not prevent the Sicilian from holding secret obedience to the one and paying tribute to the other.

Other nations have had, and still have, their bandits. The Kabyles of the Atlas Mountains, the Kurds of Armenia, and the Hillmen of Afghanistan and India are subjects of contemporary interest. Russia, in the seventeenth century, brought forth a great brigand—Stenko Razin, a Cossack, who ravaged the valleys of the Don and the Volga and the shores of the Caspian. In 1670 he headed an insurrection of the serfs in southeastern Russia, took the towns of Astrakhan, Saratov, and Samara, and devastated the country around Nizhni-Novgorod and Tombov. He was defeated in 1671, captured, and executed.

The type of brigandage combining patriotism with plunder as practiced in the Balkan States received a remarkable illustration in the last part of 1901 and the spring of 1902. On Sept. 3, 1901, as Miss Ellen M. Stone, a missionary at Bansko, in Macedonia, was traveling through the mountains, accompanied by a native woman and an escort of seven men, the party was attacked by brigands, and Miss Stone and her companion, Madame Tsilka, were carried off, while the others were sent on to Samakov to tell of the capture and to state that a ransom of \$110,000 was demanded for the release of the women. It soon became evident that the party which had captured Miss Stone were no mere brigands, but were acting as the agents of the Macedonian Committee, whose object is to free their country from the Turkish rule and who resorted to this means to secure the funds necessary for carrying on their agitation. Efforts to run down the brigands proved fruitless, and finally the United States government was forced to treat with them through its diplomatic representatives in Turkey. On February 6 a ransom of \$72,000 was paid, and on February 23 Miss Stone and her companion were set at liberty near Strumitza, not far from the place where they had been captured. The good character of the brigands was attested by the released women, who declared that they had been treated with all kindness and consideration consistent with the relation of captors and prisoners.

The United States has its share to add to the

history of brigandage Following the discovery of gold in California in 49, a succession of bandit bands, recruited largely from among the expatriated Mexicans, ravaged the mining camps and postal and express routes for many years. Other bands sprang up to the east of the Rockies, mauling and robbing until suppressed or exterminated by vigilance committees. The

"Wild Bunch," with its headquarters in the Big Horn Mountains in Wyoming, was one of the most notable of these. It began its operations in the days of stagecoaches and with the coming of the railroad became a band of train robbers. The last member of the gang was finally killed only in 1903. Jesse James, train robber from 1870 to 1881, was probably the most daring, certainly the most famous, of American bandits. His exploits have been made the subject of many stories and are as famous in England as in the United States. These names seem already to belong to a long-past age, and yet to-day records of fresh train robberies are still coming in from some of the less prosperous Southern States. Brigandage in the United States is dying out, as economic and political conditions offer steadily less occasion for it.

Mexico, with its unsettled government, is, and probably will be for some years to come, the centre of the brigandage of America.

Bibliography. Nicotri, *Mafia e brigantaggio in Sicilia* (Rome, 1900); McFarlane, *Lives and Exploits of Banditti and Robbers* (London, 1837). For an interesting account of an American bandit, consult Irwin and Jennings, *Beating Back* (New York, 1914).

BRIG'ANDINE, or BRIG'ANTINE (from *brigand*, a foot soldier, later brigand). In armor, an assemblage of small plates of iron, sewed upon quilted linen or leather and covered with a similar substance forming a sort of coat or tunic. It was lighter than the corselet, more effective than the hauberk, and cheaper than either, so that it came into common use. The brigandine was named from the brigands, a light-armed, irregular soldiery of the fourteenth and fifteenth centuries, resembling the Turkish Kurds and Bashi-bazouks of recent days, and, like them, addicted to marauding and pilfering, hence the English word "brigand." It did not come into use until the fifteenth century.

BRIGANTINE. See BRIG.

BRIGANTIUM. See BRIANCON.

BRIGGS, CHARLES AUGUSTUS (1841-1913). An American theologian. He was born in New York City, Jan. 15, 1841, studied at University of Virginia, graduated at Union Theological Seminary, New York, 1863, studied at University of Berlin, Prussia, 1866-69, and was ordained (Presbyterian) 1870. He was pastor at Roselle, N. J., from 1870 to 1874, professor of Hebrew and cognate languages in Union Theological Seminary, New York, 1874-91, and subsequently professor of biblical theology in the same institution. His inaugural address on taking this latter chair (Jan. 20, 1891), on *The Authority of the Holy Scriptures*, contained statements respecting the Bible, inspiration, and the place of reason in religion which were the subject of charges for heresy before the Presbytery of New York, which, however, after a six weeks' trial, acquitted him (December, 1892). Those who were dissatisfied with this verdict brought his case before the General Assembly of the Presbyterian church in May, 1893, and by that body he was suspended from the minis-

try, but the Seminary refused to remove him. He entered the ministry of the Protestant Episcopal church in 1897. He was the author of *Biblical Study* (1883), enlarged and rewritten, and entitled *General Introduction to the Study of Holy Scripture* (1899), *American Presbyterianism Its Origin and Early History* (to 1775), together with an appendix of letters and documents which have recently been discovered (1885), *Messianic Prophecy A Study of the Messianic Passages of the Old Testament* (1886), *Whither? A Theological Question for the Times* (1889), *The Bible, the Church, and the Reason* (1892), *The Higher Criticism of the Leviteuch* (1893), *The Messiah and the Gospels* (1894), *The Messiah of the Apostles* (1895), *General Introduction to the Study of Holy Scripture* (1899), *The Incarnation of the Lord* (1902), *New Light on the Life of Jesus* (1904), *The Ethical Teaching of Jesus* (1904), *A Critical and Exegetical Commentary on the Book of Psalms*, with Emily Grace Briggs (2 vols., 1906-07), *Church Unity* (1909), *The Fundamental Christian Faith* (1913), *Theological Symbolics* (1914). He was one of the authors of *The New Hebrew Lexicon* (1906) and one of the editors of two important series of books, *The International Theological Library* and *The International Critical Commentary*.

BRIGGS, CHARLES FREDERICK (1804-77). An American journalist and author, well known under the pseudonym of "Harry Franco." He was born at Nantucket, Mass. In 1844 he started at New York the *Broadway Journal*, of which in the following year Edgar Allan Poe became associate editor. His next important editorial work was on *Putnam's Magazine* (1853-56) in connection with George William Curtis and Parke Godwin. Later he served on the *Times*, the *Evening Mirror*, the *Brooklyn Union*, and, finally, the *Independent*. His *Harry Franco A Tale of the Great Panic* (1839) was followed by a series of works dealing more or less humorously with life in New York City.

BRIGGS, FRANK OBADIAH (1851-1913). An American legislator, born in Concord, N. H., and a graduate of the United States Military Academy. In 1877 he resigned from the army and began service with John A. Roebling's Sons Co., of which he was assistant treasurer from 1883 until his death. He was mayor of Trenton, N. J., in 1899-1902, State Treasurer in 1902-07, and United States Senator in 1907-13. He failed of reelection in 1912. For the last nine years of his life he was chairman of the Republican State Committee of New Jersey.

BRIGGS, GEORGE NIXON (1796-1861). An American lawyer and politician. He was born in Adams, Mass., was admitted to the bar in 1818, and soon attained great prominence as a criminal lawyer. He served in Congress from 1831 to 1843 and as Governor of Massachusetts from 1844 to 1851. He was subsequently a judge of the Common Pleas (1851-56), was one of the founders of the Republican party in his State, and for 16 years was a trustee of Williams College. Consult Richards, *Great in Goodness* (Boston, 1866).

BRIGGS, HENRY (1561-1631). An English mathematician, born at Warley Wood, in Yorkshire. He received his education at Cambridge, where he became examiner and lecturer in 1592. In 1596 he was made professor of geometry in the newly founded Gresham College, London, and in 1610 was invited to fill the chair of

astronomy at Oxford, but resigned this position in 1620. Briggs made a number of interesting contributions to mathematics and astronomy, but he is justly celebrated for his invention of the ordinary decimal system of logarithms. In 1616 he went to Scotland to see Napier, with whom the general idea of logarithms had originated some time previously. "My Lord," he said to Napier, "I have undertaken this journey purposely to see your person, and to know by what engine of wit or ingenuity you came first to think of this most excellent help unto astronomy, viz. the logarithms, but, my Lord, being by you found out, I wonder nobody else found it out before, when now known it is so easy." (Lilly, *History of his Life and Times*.) Briggs devoted many years of his life to the calculation of logarithmic tables, his system being still known as Briggs's Logarithms. His published works include: *Logarithmorum Chilias Prima* (1617); *Lucubrations et Annotations in Opera Posthuma J. Neperi* (1619); *Arithmetica Logarithmica* (1624); *Trigonometria Britannica* (1633). See LOGARITHMS.

BRIGGS, LYMAN JAMES (1874-). An American physicist, born at Assyria, Mich. He was educated at Michigan Agricultural College, the University of Michigan, and Johns Hopkins. In 1896 he took charge of the Physical Laboratory Division (now Bureau) of Soils in the United States Department of Agriculture, and in 1906 he became the physicist in charge of the Physical Laboratory of the Bureau of Plant Industry. His investigations published as bulletins of the Department of Agriculture include the following: *The Mechanics of Soil Moisture* (1897); *The Centrifugal Method of Soil Analysis* (1904); *The Moisture Equivalents of Soils* (1907); *Dry Farming in Relation to Rainfall and Evaporation* (1910); *The Wilting Coefficient for Different Plants and its Indirect Determination* (1912).

BRIGHAM, brig'am. A city and the county seat of Box Elder Co., Utah, 21 miles north of Ogden, on the Oregon Short Line and the Southern Pacific railroads (Map: Utah, B 1). It contains a public library and a trout hatchery. The city is engaged principally in fruit growing, being especially noted for its peaches, and has canning and cement factories, planing mills, and lumber yards. The water works and electric light plant are owned and operated by the municipality. Pop., 1890, 2139; 1900, 2859; 1910, 3685.

BRIGHAM, ALBERT PERRY (1855-). An American geologist, born at Perry, N. Y. He was educated at Colgate College, Hamilton Theological Seminary, and Harvard University. Having been ordained to the Baptist ministry, he held pastorates at Stillwater, N. Y. (1882-86), and Utica, N. Y. (1885-91). In 1892 he became professor of geology at Colgate, was for several years instructor in the Harvard Summer School of Geology, professor in the Cornell Summer School (1901-04), professor at the University of Wisconsin (1906), and lecturer at Oxford University School of Geography (1908). Besides having been editor of the *Bulletin of the American Geographical Society*, he is author of *A Text-Book of Geology* (1900); *Geographic Influences in American History* (1903); *Student's Laboratory Manual of Physical Geography* (1904); *From Trail to Railway through the Appalachians* (1907); *Commercial Geography* (1911).

BRIGHAM, AMARIAH (1798-1849). An American physician, who devoted much attention to the study of insanity. He was born in New Marlboro, Mass., and was eminent as a physician in that State and at Hartford, Conn., where he became superintendent of the retreat for the insane in 1840. Two years later he accepted a similar post at the New York State Asylum in Utica, N. Y. Dr. Brigham regarded infant schools and religious revivals as frequent inducers of insanity, and published his views in *Influence of Mental Cultivation on the Health* (1832) and *Influence of Religion upon the Health and Physical Welfare of Mankind* (1835). He also established the *Journal of Insanity* and published *Treatise on Epidemic Cholera* (1832) and *Diseases of the Brain* (1836).

BRIGHAM, WILLIAM TUFTS (1841-). An American ethnologist and museum director, born in Boston. After graduating from Harvard, he investigated the botany of the Hawaiian Islands in 1864-65, was for several years an instructor at Harvard, and while a member of the Boston school board brought about the introduction of art instruction in the public schools. In 1888 he became director of the Bishop Museum of Ethnology in Honolulu. His publications include: *Cast Catalogue of Antique Sculpture* (1874); *Guatemala, the Land of the Quetzal* (1887); *Hawaiian Feather-Work* (1890); *Mats and Baskets of the Ancient Hawaiians* (1906); *Ancient Hawaiian House* (1908); *Ka Hana Kapa (Bark Cloth Making)* (1911).

BRIGHAM YOUNG UNIVERSITY. A coeducational institution under control of the Latter Day Saints at Provo, Utah. It was founded by a deed of trust executed by President Brigham Young in 1875. It has collegiate, normal, and high-school departments. The total enrollment in all departments in 1913 was 650; the faculty numbered 30. There were about 6000 volumes in the library. President, George H. Brimhall.

BRIGHELLA, brèg'èl'la (It. dim. of *briga*, strife, quarrel, brawl). A rustic clown; one of the conventional types in old Italian comedy.

BRIGHOUSE. A town in the West Riding of Yorkshire, England, on the Calder, about 3 miles east-southeast of Halifax (Map: England, E 3). It is composed of the districts of Brighouse, Rastrick, and Hove Edge, which were incorporated in 1893 as a borough. Its water is supplied by the corporation of Halifax. The town owns gas and electric light plants, markets, a free library, art gallery and museum, a sewage-disposal works, and cemeteries. Its industries consist of the manufacture of woolen, worsted, and silk fabrics. There are also machine works and stone quarries. Pop., 1891, 20,666; 1901, 21,735; 1911, 20,843. Consult Turner, *History of Brighouse* (Bingley, 1893).

BRIGHT, SIR CHARLES TILSTON (1832-88). An English engineer, born at Wanstead. In 1852 he became connected, in the service of the Magnetic Company, with the laying of underground systems of land telegraphy. He took out patents on telegraphic apparatus and in 1856 was appointed engineer in chief to the Atlantic Cable Company. After two failures he at length succeeded, on Aug. 5, 1858, in laying the 2050 miles of cable connecting Ireland and Newfoundland. (See ATLANTIC TELEGRAPH.) He was thus the first to establish communication by telegraph between America and Europe. Subse-

quently he was employed in the laying of cables in the Mediterranean Sea, in the Persian Gulf, and among the West Indies. From 1865 to 1868 he represented Greenwich in Parliament as a Liberal, and in 1866-67 was president of the Institute of Electrical Engineers. With Latimer Clark he invented a method for the application of a composition of asphalt as a coating for the exterior of submarine cables.

BRIGHT, JAMES FRANCK (1832-) An English scholar, educator, and author. He was born at St. James's, Westminster, graduated in 1855 at University College, Oxford, and from 1856 to 1872 was an assistant master at Marlborough College. In 1872 he became tutor and lecturer in modern history and divinity at Balliol, and lecturer in modern history at University College. Of the latter, he was in 1874 appointed dean, and from 1881 to 1906 was master. He was repeatedly examiner in history at the university. He published a textbook, *History of England to 1901* (5 vols., 1884-1904), and lives of Joseph II and Maria Theresa, both in 1897.

BRIGHT, JAMES WILSON An American philologist, educated at Lafayette College and at Johns Hopkins (Ph D., 1882). By the latter institution he was appointed associate professor of English philology (1891), professor (1893), and professor of English literature (1905). Prominent in the movement for "spelling reform," like his teacher March at Lafayette, he became a vice president of the London Simplified Spelling Society. He edited *Anglo-Saxon Reader, with Outlines of Grammar* (1891), *The Gospel of St. Luke in Anglo-Saxon* (1893), and, in West Saxon, *St. Matthew* (1904), *St. John* (1904), *St. Mark* (1905), *St. Luke* (1906), and, with other editors, *The Psalms* (1907). He collaborated with R. D. Miller on *Elements of English Versification* (1910), and with G. L. Kittredge edited *The Albon Series of Anglo-Saxon and Middle English poetry* (1906 et seq.). He was also chosen an editor of the *Notes of the Modern Language Association*.

BRIGHT, JESSE D. (1812-75) An American politician. He was born in Norwich, N. Y., but removed with his parents to Indiana in 1820, was admitted to the bar in 1831, and was successively a member of the State Legislature, Lieutenant Governor of the State, and United States Marshal. In 1845 he was elected to the United States Senate and thereafter on several occasions was chosen as its President pro tem. He was an enthusiastic Democrat and in all sectional disputes consistently voted with the South against the North. In 1862 the Republicans brought against him a charge of disloyalty, which was based largely on his having written to "His Excellency Jefferson Davis, President of the Confederation of States," a letter introducing a friend who had an "improvement in firearms" to dispose of, and though the Judiciary Committee decided that such evidence as had been adduced was insufficient for conviction, nevertheless he was expelled from the Senate by a vote of 38 to 14. He subsequently went to Kentucky, where he was elected to the State Legislature, and in 1874 he removed to Baltimore, Md.

BRIGHT, JOHN (1811-89) An English statesman and orator. He was the son of Jacob Bright, a Quaker cotton spinner and manufacturer at Rochdale, Lancashire, and was born at Greenbank, near that town, Nov. 16, 1811. Young Bright's education was of a fitful and elementary character, and the magnificent attainments which

he displayed in later life must be ascribed entirely to native talent and to indefatigable industry. At the age of 15 he entered his father's business, but devoted himself at the same time to the study of public oratory, which seems to have attracted him at a very early period. In 1835 he made a foreign tour, which included a journey to Palestine. On his return he delivered a number of lectures on the subject of his travels and on topics connected with commerce and political economy before the Literary Society of Rochdale, of which he was one of the founders. As a manufacturer, and as a believer in the orthodox political economy of his day, Bright opposed determinedly the humanitarian efforts of the Tory Socialists (qv) to stamp out the evils of child labor. His remedy for the horrible conditions within the English factory was to repeal the corn laws and to inaugurate free trade—a remedy which, be it noted, the manufacturers embraced with the more enthusiasm inasmuch as it entailed hardships upon the landowners alone, while at the same time it exempted themselves from all responsibility. In 1839 he was one of the founders of the first Anti-Corn Law Association at Manchester, at which time he made the acquaintance of Richard Cobden, with whom he lived in close friendship till the latter's death. Bright, however, did not actively enter into the Anti-Corn Law agitation until 1841, but from that time until the repeal of the laws in 1846, he and Cobden were the most prominent leaders of the movement, and Bright continued, by the side of Cobden, to be one of the chief pillars of the general system of free trade, which obtained such complete ascendancy in England. Bright's power consisted in his talent for forceful presentation, which made him an excellent popular exponent of the principles formulated by finer thinkers, like Cobden. In 1843 Bright was elected to Parliament from Durham, and four years later from the factory town of Manchester, for by this time he had come to be regarded as one of the leaders of English workmen. After 1857 he sat for Birmingham. In Parliament Bright, though initiating no important measures of legislation himself, exercised a very powerful influence on the most important features of Imperial policy. He showed himself an ardent champion of the rights of the people of India, in their defense he antagonized the East India Company, and he was largely instrumental in bringing India under the direct control of the crown. He also lent much attention to the Irish question. He was a warm advocate of the disestablishment of the Irish church and to the end of his life was interested in the various Irish land measures. He remained a leader of the Liberal party throughout his life, playing a great part in the movement which led to the Reform Bill of 1867, and, in a somewhat less degree, in the agitation preceding the County Franchise Bill of 1884. He held office under Gladstone as President of the Board of Trade from 1868 to 1870, and as Chancellor of the Duchy of Lancaster from 1873 to 1874 and from 1880 to 1882. In 1883 he was made Lord Rector of Glasgow University. He died March 27, 1889.

The enormous influence which Bright exercised on English politics and public opinion during the greater part of his life was due in less measure to his intellectual attainments than to his power as an orator. Aside from the gift of oratory, which, according to competent crit-

ies, he possessed to a degree unequalled by any other English statesman of the nineteenth century, Bright impressed himself upon Parliament, and more than that, upon the people at large, by the intense earnestness, the hatred of injustice, and the disinterested sympathy for the oppressed which he displayed at all times. He has been characterized as having had in him something of the austerity of the ancient Hebrew prophets, and he certainly spoke like one who brings his religion into his politics. Though called the "Tribune of the People," he never feared to antagonize public opinion whenever that opinion was out of conformity with his rigid standards of duty and right. Thus, being in general opposed to all war (as a result no doubt of his Quaker origin), he dared to advocate peace with Russia in 1854 at a time when the war fever was at its height; and again, in 1877-78, he stood opposed to British intervention in Russo-Turkish affairs. To America, especially, Bright rendered services of inestimable value during the period of the Civil War, in that he was undoubtedly the most prominent among the very few notable men, in Parliament or out, who advocated the cause of the North against the South; and that, too, in spite of the fact that the continuance of the war was disastrous to his own interests as a cotton spinner and to the entire Lancashire cotton trade. But his moral power was most clearly shown in the period after the conversion of the Liberal party to Home Rule in 1885. Mr. Bright, regarding such a policy as vicious, refused to follow his old leader, Gladstone, and did not hesitate to denounce openly the "unholy alliance," as he considered it, of the old Liberal party with the Parnellites, although to him this meant the breaking up of ancient personal and political ties which effectually saddened the last years of his life. A collection of Bright's speeches was published at London in 1898 and his *Public Letters* in 1895. Consult: Barnett-Smith, *Life and Speeches of John Bright* (New York, 1881); Robertson, *Life and Times of John Bright* (London, 1902); Trevelyan, *The Life of John Bright* (London, 1913).

BRIGHT, RICHARD (1789-1858). An English physician, born in Bristol. He was educated at Edinburgh, London, Berlin, and Vienna, and after 1820 was connected with Guy's Hospital, London. He conducted many important investigations in the field of pathological anatomy and was the first to discover the true nature of the disease since known by his name. (See **BRIGHT'S DISEASE**.) He published *Original Researches into the Pathology of Diseases of the Kidney* (1827), and a book of *Travels through Lower Hungary* (1818), which contains a valuable account of the gypsies.

BRIGHT, WILLIAM, D.D. (1824-1901). An English Church historian. He was born at Doncaster, England, Dec. 14, 1824, and was educated at Rugby and University College, Oxford. He was ordained a priest in 1850, and for nine years was a theological tutor at Trinity College, Glensmond. Returning to Oxford as tutor, he became in 1868 canon of Christ Church and regius professor of ecclesiastical history. He published editions of several Church fathers. Among his numerous original works may be mentioned: *History of the Church, from the Edict of Milan to the Council of Chalcedon* (1860); *Chapters of Early English Church History* (1878); *Notes on the Canons of the First*

Four General Councils (1882); *The Roman See in the Early Church* (1896); *Some Aspects of Primitive Church Life* (1898). He died at Oxford, March 6, 1901.

BRIGHTENING. In calico printing, the operation of rendering the colors of printed fabrics more bright or brilliant by treating them in solution of soda, acids, or other materials.

BRIGHTLY, FREDERICK CHARLES (1812-88). An American lawyer, born at Bungay, Suffolk, England. He came to America in 1831, studied law, was admitted to the bar in 1839, and from 1870 was wholly occupied with legal authorship. His collection of 5000 volumes was considered one of the best private law libraries in the United States. His many compilations include: *Law of Costs in Pennsylvania* (1847); *A Digest of the Decisions of the Federal Courts* (2 vols., 1868-73); *Leading Cases on the Law of Elections* (1871); *A Digest of the Decisions of the Courts of the State of New York to January, 1884* (3 vols., 1875-84).

BRIGHTON, br'v-ton (originally *Brightelmstone*, named after an Anglo-Saxon bishop, *Brightelm*, who was supposed to have founded it in the tenth century, + *town*). A town and celebrated seaside resort, styled "London by the Sea" and "The Queen of Watling Places" in Sussex, England, on the English Channel, 51 miles south of London (Map: England, F 6). It is built on a slope ascending eastward to a range of high chalk cliffs bounding the coast as far as Beachy Head; to the west these hills recede from the coast and leave a long stretch of sands. It extends from Kemp Town on the east to Hove on the west. The town has suffered severely at various periods of its existence through inroads of the sea, and to guard against further encroachments, a great sea wall has been built; further protection is furnished by numerous jetties projected seaward. A fine promenade, called the Front, the largest seaside promenade in Great Britain, extends along the sea front for 4 miles. Brighton is well built and possesses many handsome buildings, among them being several palatial hotels. Near the centre of the town is the Royal Pavilion, a fantastic Oriental or Chinese structure, with domes, minarets, and pinnacles, built for the Prince of Wales (afterward George IV) and acquired by the town in 1850. It contains assembly rooms, a museum, picture galleries, etc. The Dome, formerly the Royal Stables, also acquired by the town, has been turned into a magnificent concert hall. The aquarium is world-famous, and the Booth Museum (bequeathed to the town in 1890 by E. T. Booth) contains the finest collection of British birds in existence. There are numerous theatres and music halls.

Brighton obtained its charter of incorporation in 1854. It sends two members to Parliament. The town owns its excellent water supply, as well as its electric light plant, which yielded in 1909-10 a profit of about \$300,000. Among other municipal undertakings are an electric street-car service, public baths, markets, and slaughterhouses. The town has numerous parks and public race grounds. In addition to its numerous private schools, the town has a municipal school of science and technology, and one of art, a grammar school, and a public library. Brighton has no maritime trade. It is essentially a town for recreation and sea bathing. There are several hospitals, including one for children, a blind and a deaf-and-dumb asylum.

An electric street railroad connects Brighton with Kemp Town, and an electric shore road (overhead trolley) with Rottingdean Pop, 1891, 115,873, 1901, 123,478, 1911, 131,250 Brighton was an important place in the sixteenth century, when it was twice ravaged by the French. The sea, however, now covers the ground where old Brighton once stood.

Consult Sicklemore, *History of Brighton* (Brighton, 1827), Sawyer, "Old Brighton," in *Archæological Journal*, vol. xlii (London, 1886), "Progress of Brighton," in *Municipal Journal* (London, 1899), Melville, *Brighton Its History, its Folks, and its Fashions* (London, 1909).

BRIGHT'S DISEASE The common name for *nephritis*, or disease of the kidneys. It takes its name from Dr. Richard Bright (q.v.), an English physician, who in 1827 first recognized and described renal disease and properly attributed to it the symptoms and the changes in the urine which it causes. The term is not distinctive, for it includes several forms of *nephritis*. For clinical purposes diseases of the kidneys are classified according to the nature of the morbid process existing, whether it be congestion, degeneration, or inflammation. These processes are attended by accumulation of blood in veins and capillaries of the kidneys, changes in their blood vessels and tissues, formation of new tissue and death of tissue, with resulting local and general symptoms and disturbances of function. We have, then, acute and chronic congestion of the kidney, acute and chronic degeneration of the kidney, acute and chronic exudative *nephritis*, acute productive *nephritis*, chronic *nephritis*, without exudation, suppurative *nephritis*, and tubercular *nephritis*. There are many synonymous names for these diseases. The *causes* of *nephritis* may be as follows: (1) prolonged exposure to cold, (2) poisons, such as alcohol, turpentine, cantharides, lead, arsenic, mercury, as well as the toxins produced during yellow fever, scarlet fever, gout, syphilis, suppuration, tubercle, cancer, etc., (3) mechanical obstruction to the circulation, such as heart disease and pleurisy with effusion. The *symptoms* of *nephritis* differ. In acute *nephritis* the patient may have merely slight headache, pain in the back and in the legs, loss of appetite and nausea, or he may have fever, prostration, stupor, twitching, shortness of breath, and convulsions. The urine generally contains albumen and casts, and there may be dropsy of the legs. In the chronic forms of the disease the symptoms are less severe, though shortness of breath, severe headache, anæmia, and dropsy generally predominate. In the *treatment* of *nephritis* physicians generally recommend frequent change of scene and climate, reduction of sugars and starches and increase of fats in the diet, abstinence from alcoholic beverages and from tobacco, and life in the open air. Drugs are of much less value.

Pathology In *acute congestion* the kidneys are swollen and darker than normal, the vessels containing an increased amount of blood. There may be flattening of the tubules from pressure and exudation into them. In *acute degeneration* the kidney is usually somewhat enlarged, it may be congested, and the cortical portion is often swollen and pale. The cells of the kidney tubules are swollen and granular and show various stages of disintegration, up to complete destruction of the cells. Within the tubules are fat globules, coagulated albumen, and gran-

ular matter, resulting from degeneration of the epithelium. In *acute exudative inflammation* the condition of the kidneys varies greatly. There may be simply congestion, with inflammatory products in the tubules. The kidney may be enlarged and congested, the cortex, thick, pale, and wet. The epithelium of the tubules is apt to be swollen or flattened by the exudate or disintegrated, and there are collections of white blood cells scattered throughout the cortex. In the lumina of the tubules are masses of coagulated albumen, casts (either clear or containing red or white blood cells), and the products of cellular disintegration. In the glomeruli of the kidneys there is a thickening of the capsule epithelium and of the cells lining the capillaries, so that the outlines of the capillaries disappear. There is often an accumulation of coagulated albumen and detritus within the cavity of the glomerulus. In *acute productive inflammation* the kidneys are increased in size, the surface smooth, and the capsule non-adherent. An acute exudative inflammation such as has just been described is usually present, but added to this is an increase in the connective tissue elements of the kidney, with consequent atrophy of the tubules. There may be extreme proliferation of the capsule cells of the glomeruli. The kidneys remain permanently damaged organs.

In *chronic congestion* the kidney is somewhat enlarged, heavy, hard, of dark-red color, the surface smooth, and the capsule non-adherent. The epithelial cells of the tubules may be swollen, and in the glomeruli the capillaries are distended, with thickening of their walls. In chronic degeneration, due to heart disease, the kidneys are usually large and white, the cortex being thickened. The epithelium of the tubules is swollen and granular, and in the glomeruli the capsule cells are distended. In the degeneration which occurs in wasting diseases the changes in the glomeruli are apt to be absent, while in senile degeneration the kidney may be either large and white, or small, red, and atrophied, with changes in the epithelium of the tubules, but no change in the glomeruli. In *chronic diffuse inflammation with exudation*, or *chronic parenchymatous inflammation*, the appearance of the kidney varies greatly. It is usually enlarged, more rarely it is of normal size or small. Its surface may be smooth or nodular. The cortex may be thickened and white, or mottled. The epithelium of the tubules may be flattened by exudate, or swollen and granular. Some tubules are of normal size, others are dilated, while still others are compressed by the new connective tissue. Within the lumina are coagulated albumen, disintegrated epithelium, and red and white blood cells. In the glomeruli there is an increase in the connective-tissue elements with atrophy, and the capillaries may show waxy degeneration. There is an increase in the interstitial connective tissue of the kidney, but it is not extensive. The arteries often show increased thickness of walls. In *chronic diffuse inflammation*, without exudation, or *cystic* of the kidney, the kidney is apt to be small, its surface rough, and its capsule adherent. The increase in connective tissue is the most marked feature. Dependent upon or determining this increase in connective tissue is atrophy of the tubules and of the glomeruli. The tubules are sometimes greatly swollen and form casts. The blood-vessel walls are usually thickened, and the capillaries of the glomeruli

may show waxy changes. Consult Osler, *Principles and Practice of Medicine* (New York, 1912). See ALBUMINURIA; KIDNEY.

BRIGITTINES, brî'tî-tînz, or ORDER OF OUR SAVIOUR. An order founded in 1346, as a branch of the Augustinians, by St. Bridget, or Brigitta, of Sweden. It took in both men and women. The first monastery, which was also the mother house of the order, was on the founder's estate at Vadstena, on the eastern bank of Lake Vättern, southwest of Stockholm. At the other houses of the order the monks and nuns inhabited contiguous buildings, but never saw each other, and each sex governed its own affairs. Their occupations were largely literary, and they prepared Swedish translations of religious works, mostly of evangelical tendency. The order spread through Scandinavia and Finland, also into Holland, Germany, Italy, and Spain. Henry V (1413-22) introduced it into England and founded Sion House, near Brentwood, 7½ miles west of London. Henry VIII suppressed it, with other religious orders. Mary reestablished it, but Elizabeth again suppressed it. The nuns then went to Portugal and opened their house in Lisbon. In 1861 some of their successors came back and opened a house in Spetisbury, Dorsetshire. Later on it was moved to its present site, Chudleigh, near Exeter. In Sweden the order had so firm a hold that the mother house was not suppressed till 1595, when most of the houses outside had ceased to exist. The order was revived in Belgium as Brothers of the Revised Brigittine Order, and in Spain as Nuns of the Order of St. Bridget, and there it has now five convents. Only four convents of the original order now are found—one in Bavaria, at Altmünster, two in Holland, and the one mentioned in England. For the history of the order in Sweden, consult *Scriptores Rerum Suevicarum Medii Aevi*, vol. i (Stockholm, 1871); also *History of the English Brigittine Nuns* (Plymouth, 1886), and Steele, *Story of the Brigittines* (New York, 1911). The Basel reformer Geolampadius was a Brigittine monk.

BRIGLIADORO, bré'lyá-dô'rô (It. from *briglia*, bridle + *d'* = *di*, of + *oro*, Lat. *aurum*, gold). The name given to Orlando's steed in Boiardo's *Orlando Innamorato*, on account of the splendor with which he was bridled.

BRIGNOLES, bré'nyô'l'. The capital of an arrondissement in the department of Var, France, on the Calami, 22 miles southwest of Draguignan (Map: France, S, I 5). It is picturesquely situated in a fertile valley, surrounded by forest-clad hills, and has some fine old buildings. The palace of the counts of Provence is occupied by the prefecture; the Templars' house is now a theological seminary. Brignoles has tanneries, potteries, silk, woolen, and cloth manufactures, and a trade in brandy, wines, prunes, and olives. The town was known as Villa Puerorum in connection with the rearing of the children of the counts of Provence. It was captured and sacked by Charles V in 1524 and by the Leaguers in 1628. Pop., 1901, 3904; 1911, 3692.

BRIGNOLI, bré-nyô'lé, PASQUALE (1824-84). An Italian tenor, born in Naples. He received an excellent musical training, at first in piano and later in singing. He appeared with great success in concert and opera, in Paris, London, and the principal cities of Europe; then came to the United States, under Strakosch, in

1855, and for a quarter of a century was one of the most popular operatic tenors. He sang with Patti at her début and appeared with all the great singers of his time—Parepa-Rosa, La Grange, Tietjens, and Nilsson among them. Brignoli's voice was a true tenor of beautiful quality, great carrying power, and wonderful flexibility. His vocalization and phrasing were of the highest order, but he lacked grace in figure and was a poor actor. He received high prices for his singing, yet he died in New York a poor man.

BRIGS OF AYR, THE. A delightfully humorous little poem by Robert Burns, reporting an imaginary colloquy between the old and new bridges (Scot. *brigs*) over the Ayr.

BRIHASPATI, brî-hûs'pâ-té, or **BRHASPATI**, br'hus'pâ-té (Skt. *Brhaspati*). A Hindu god prominent in the Rig-Veda, but of less importance in the later mythology of India. His name appears frequently also in the form *Brahmanaspati*, 'Lord of Strength,' or 'Lord of Prayer' (*brahman*), and as the incarnation of the *brahman*-lord he appears to have been the prototype of the god Brahma, the head of the later Hindu Trinity. (See BRAHMA.) Like the latter, also, he is "father of the gods," although himself begotten by Tvashtar, the artificer. He is portrayed in the Vedas as having 7 mouths, 7 rays, 100 wings, sharp horns, and armed with bow and arrows and an axe; he is ruddy and bright, dispelling the darkness; and he rides in a chariot drawn by ruddy steeds. Many of his attributes, and especially his aspect as a divine priest presiding over devotion and sacrifice, recall Agni, the god of fire, of whom he is regarded by many scholars merely as a variety. But his close connection with Indra (*q.v.*) in the Vedic hymns leads others to consider Brihaspati in his sacerdotal character as a priestly abstraction of Indra. In later times of the epic and the Puranas he is represented as a Rishi, or divine seer, and preceptor of the gods. He is regent of the planet Jupiter, with which his own name is commonly identified. His wife is Tara. Consult: Macdonell, *Vedic Mythology* (Strassburg, 1897); Strauss, *Brhaspati im Veda* (Leipzig, 1905); Formel, *Le dieu Brihaspati dans le Rîgveda* (Paris, 1898); Noble and Coomaraswamy, *Myths of the Hindus and Buddhists* (London, 1913).

BRILL (BRIL), brél. A family of Flemish landscape painters, of which the most important were Matijs and Paulus, brothers.—**MATJYS** (1550-84) was born in Antwerp and died in Rome. He was employed in the Vatican in the time of Gregory XIII, and instructed his brother Paulus, who succeeded to his pension.—**PAULUS** (1554-1626) was also born in Antwerp and died in Rome. He was one of the best of the Flemish landscape painters of his time; his influence was potent on the Italian schools of landscape painters. The poetic charm of his work may be seen as a setting to some of the figure painting executed by such masters as Annibale Carracci and Rubens. His works in oil and fresco are in many of the Roman churches. He had for patrons both Clement VIII and Sixtus V and executed many frescoes in the Vatican, the Lateran, the Scala Santa, Santa Magiore, and Palazzo Rospigliosi. Of his panel paintings the best are in Florence, Brunswick, Montpellier, Munich, Paris, Parma, and Vienna. Consult: Roose, *Geschiedenis der antwerpsche Schilderschool* (Antwerp, 1887-90); Eisler in

London, *Burlington Magazine* (1905), Mayer, *Das Leben und die Werke des Bruders Matthäus und Paul Brill* (Leipzig, 1910)

BRILL (probably Corn *brill*, mackerel, for *brithelli*, from *brith*, speckled) A species of turbot, found in considerable abundance on some parts of the British coasts, and common in the markets of the larger towns. It resembles the turbot, but is distinguished by its smaller size (18 inches), more oval outline, the want of tubercles on its upper surface, and its reddish hue. It has the same haunts and habits as the turbot, but its flesh is not thought quite so good.

BRILLAT-SAVARIN, bré'ya' sa'va'rân', ANTHELME (1755-1826) A French writer on gastronomy, noted as the author of *Physiologie du goût* (1825), beyond compare the finest literary excursion into the field of gastronomy. He was born at Belley and was a Federalist. During the Reign of Terror he fled to Switzerland, and in 1793 to New York, where he supported himself by lessons and music till his return to Paris in 1796. He held office under the Directory and during the Consulate became judge in the Court of Cassation. His book reveals the genial host and friend, full of anecdote and shrewd observation. It is delightful, also, for its mock seriousness, its conscious grandiloquence, as when he invokes "Gasteria, the tenth and fairest of the Muses," and for the bizarre arrangement of his "meditations" on *Corpulence ou la théorie de la friture*. Two translations (London, 1877, New York, n.d.) of the *Physiologie* into English are fairly satisfactory. The English title is *Gastronomy as a Fine Art*.

BRILLIANT (Fr *brillant*, sparkling, from Lat *berillus*, beryl, gem) A name popularly given to the diamond, especially when cut so that the base or flat portion, called a *table*, is surrounded by 24 facets, which extend to the girdle, or central edge, above which are 32 facets, terminating in a point called a *culet*. See DIAMOND.

BRIMSTONE A name sometimes applied to sulphur, especially in the form of sticks or rolls. It is derived from ME *brimnen*, *brennen*, to burn + *ston*, stone, sulphur having been considered by the alchemists as the principle of combustibility. See SULPHUR.

BRIN, bién, BENEDETTO (1833-98) An Italian engineer and statesman, born in Turin. He studied engineering, became a chief of section in the Ministry of Marine, and was Minister of Marine in 1876-78, 1884-91, and from 1896 until his death. From 1882 he represented Turin in the Chamber of Deputies and in 1892-93 was Minister of Foreign Affairs. He did much to promote the mechanical development of the Italian navy and himself designed several armored cruisers. His writings include *La nostra marina militare* (1881) and *Relazione intorno al materiale di navigazione e salvataggio all'Esposizione del 1878 a Parigi* (1884).

BRINCKMAN, CARL GUSTAV, BARON (1764-1847) A Swedish statesman and poet. He was born at Brunnkyrka, near Stockholm, and studied at Upsala, Halle, Leipzig, and Jena. He became successively Secretary of Legation of the Swedish embassy at Dresden (1792), chargé d'affaires at Paris (1797), chargé d'affaires at Berlin (1801), Ambassador to London (1808), and court chancellor at Stockholm (1810). His poetical works include *Småtlets värld* (1822), for which he received the first prize of the

Swedish Academy, and *Tankebilder* (1828). Consult Wachtmeister, *Budrag till Carl Gustav von Brinckmans, biografi och karaktärsbild* (Lund, 1871).

BRINDABAN, brin'da-bûn' See BINDRABAN.

BRINDISI, brén'de-zé (anciently, Lat *Brundisium*, *Brundisium*, Gk *Ἰππὸν*, *Brentesion*, said to have received its name from the harbor projecting as do the antlers of a stag, from *βρέndon*, *brendon*, deer, stag) A seaport town of southern Italy, in the province of Lecce. It is situated on a small promontory in a bay of the Adriatic Sea, about 45 miles east-northeast of Taranto (Map Italy, M. 7). Brindisi is a city of very great antiquity. It was taken, in 267 B.C., from the Sallentines by the Romans, who some 20 years later established a colony here. The town, partly owing to the fertility of the country, but chiefly on account of its excellent port—consisting of an inner and outer harbor, the former perfectly landlocked, and capable of containing the largest fleets and of easy defense on account of its narrow entrance, which is also very well sheltered—rapidly increased in wealth and importance. It soon became the principal naval station of the Romans in the Adriatic. In 230 B.C. Brindisi was the starting place of the Roman troops that took part in the first Illyrian War, and from this point the Romans nearly always directed subsequent wars with Macedonia, Greece, and Asia. The city was the regular point of embarkation for Greece and the East, by way of Dyrrachium (Epidamnus). When the Roman power had been firmly established beyond the Adriatic, Brindisi became a city second to none in south Italy in commercial importance. Paeuvius (q.v.) was born at Brindisi. Horace, who accompanied Mæcenas in a diplomatic expedition to Brindisi in 38 or 37 B.C., has made the journey the subject of one of his satires (*Sat.* i, 5). Vergil died here in 19 B.C., on his return from Greece. The city appears to have retained its importance until the fall of the Empire, but it suffered greatly in the wars which followed. When the Normans became possessed of it in the eleventh century, the Crusaders made it their chief port for embarkation to the Holy Land, but with the decline of the Crusades Brindisi sank into comparative insignificance as a naval station. The city subsequently suffered greatly from wars and earthquakes. The principal buildings are the cathedral, where the Emperor Frederick II was married to Yolande in 1225, and the castle, commenced by Frederick II and finished by Charles V. Chief among the remains of ancient times is a column, 82 feet high, one of two, which, tradition says, marked the end of the Appian Way. The district around Brindisi is still remarkable for its fertility, olive oil being produced in large quantities. Since the opening of the Suez Canal and the construction of the Mont Cenis and St. Gotthard tunnels Brindisi has greatly increased in importance, being the landing place or point of departure for numerous steamship lines. Pop, 1881, 14,508, (commune) 1901, 25,317.

BRINDLEY, JAMES (1716-72) An English engineer, born in Derbyshire. He was apprenticed at 17 to a millwright, but afterward became an engineer, and in 1752 showed great ingenuity in contriving a water engine for draining a coal mine. The machine consisted of an atmospheric force pump and was soon

offset by the steam engine. His invention of a silk mill on a new plan and several other ingenious contrivances recommended him to the Duke of Bridgewater, who employed him to build the canal between Worsley and Manchester. Thenceforth he devoted his great skill and genius to the construction of navigable canals, commencing the Grand Trunk and completing the Birmingham, Chesterfield, and others. He was quite illiterate and did most of his work in his head without written calculations or drawings. Consult Samuel Smiles, *Lives of the Engineers*, vol. 1 (London, 1861-62).

BRINE (AS. *bryne*, literally, a burning, from *beornan*, to burn). The term applied to water highly impregnated with common salt. The waters of the oceans and many inland seas represent brines of different degrees of salinity. Natural brines are found in some porous sandstones, and may represent sea water imprisoned in these rocks at the time of their deposition. This is known as *connate water*. Brine springs are those natural waters containing much salt, which in many parts of the world issue from fissures in the ground. Consult Clarke, *United States Geological Survey, Bulletin 491*, 1912. See SALT SPRING; MINERAL WATERS; OCEAN; DEAD SEA.

BRINE SHRIMP. A small branchiopod crustacean (*Artemia salina*), which, unlike the greater number of animals of that group, is an inhabitant not of fresh, but of salt water. It is found in myriads swimming about in the brine of salt pans previous to boiling, when, having been concentrated by exposure to sun and air for about a fortnight, it destroys the life of almost all other marine animals. The full-grown brine shrimp is about half an inch long. One of the most curious things about this species is that it accustoms itself so readily to changes in the density of the water which it inhabits. It has been shown by experiment that if sufficient care is taken these animals can, after a number of generations, live in perfectly fresh water; but, more remarkable still, it will then be found that they are no longer *Artemia* at all, but resemble *Branchipus stagnalis*, a common fresh-water branchiopod, generically different from *Artemia*. This has been cited as a direct experimental proof of evolution, and as showing admirably the great effect of the environment upon the form and structure of animals. See PHYLLOPODA.

BRINFAREE (brin-já-ré) DOG. The Indian greyhound. See GREYHOUND.

BRINK, BERNHARD TEN (1841-92). A German philologist. He was born in Amsterdam and studied in Münster (1861-62) and Bonn (1862-65). He was professor of modern languages at the University of Marburg (1870-73) and professor of English at Strassburg (1873-92). Among his works are the following: *Chaucer, Studien zur Geschichte seiner Entwicklung*, vol. 1 (1870); *Geschichte der englischen Literatur*, vol. 1, Chaucer to Wiclif (1877; Eng. trans. by H. M. Kennedy, 1883); vol. ii, from Wiclif to the accession of Elizabeth (1896), in some respects the best history of English literature extant; *Chaucers Sprache und Verskunst* (1884; 2d ed., 1890; Eng. trans. by M. B. Smith, *The Language and Metre of Chaucer*, 2d ed., rev., 1901); *Beowulf, Untersuchungen* (1888); *Shakespeare: Fünf Vorlesungen* (1893; Eng. trans. entitled *Five Lectures on Shakespeare*, by Julia Franklin, 1895). He also published editions of Chaucer's *Prologue to the Canterbury Tales*

(1871), and of the *Complaynte to Pite* (among the writings of the Chaucer Society, London). From 1874 to the year of his death, he was editor of the *Quellen und Forschungen zur Sprach- und Culturgeschichte der germanischen Völker*.

BRINK, JAN TEN (1834-1901). A Dutch scholar and author, born in Appingedam. He studied theology in Utrecht, went in 1860 as tutor to Batavia, from 1862 to 1884 was instructor in the Dutch language and literature in the Gymnasium of The Hague, and in the latter year was appointed professor of the history of Dutch literature in the University of Leyden. His works, composed chiefly of studies in literary criticism, and stories, include: *Bulwer Lytton, Biografie en Kritiek* (1873); *Letterkundige schetsen* (2 pts., 1874-75); *Geschiedenis der Noord-Nederlandsche letteren in de XIX. eeuw* (3 vols., 1888-89; new ed., 1904); *Romans en novellen* (13 vols., 1885). His complete works in belles-lettres have appeared in 17 vols., as *Litterarische schetsen en kritieken* (Leyden, 1882-88).

BRINK'ERHOFF, ROELIFF (1828-1911). American banker, philanthropist, and penologist, born in Owasco, N. Y., June 28, 1828. He was for years the central figure in the National Prison Congresses as well as a prominent worker in the National Conferences of Charities and Correction. From 1878 until the time of his death he was a member of the State Board of Charities of Ohio and for many years its chairman. Through his efforts the public charitable and penological work in Ohio was maintained at a high level of efficiency. General Brinkerhoff enlisted in the volunteer army in the Civil War, attained the rank of colonel, and was breveted brigadier general for meritorious service. He was the author of *The Volunteer Quartermaster*, and *Recollections of a Lifetime* (1900), as well as of numerous articles and published addresses on philanthropic subjects.

BRINKLEY, FRANK (1844-1912). An English editor. While still a young man he went to Japan and there in 1867 had command of the Royal Artillery, in 1871 was principal instructor in the Marine Artillery College at Tokio, and later was professor of mathematics at the Imperial Engineering College. He became proprietor and editor of the *Japan Mail* in 1881, and continued to edit this journal until the year of his death. One of the leading authorities on matters relating to Japan, he was made foreign adviser to the Nippon Yusen Kaisha and Tokio correspondent of the London *Times*, and published *Japan* (1901), *Japan and China* (1903), *Unabridged Japanese-English Dictionary*, and articles on Japan in encyclopedias. The Japanese Order of the Sacred Treasure was conferred upon him.

BRINTON, DANIEL GARRISON (1837-99). An American archaeologist and ethnologist. He was born at Thornbury, Pa., graduated at Yale in 1858 and at Jefferson Medical College in 1861, and subsequently studied in Paris and Heidelberg. He served in the army as a surgeon, was editor of the *Medical and Surgical Reporter* from 1867 to 1887, and became professor of ethnology at the Philadelphia Academy of Natural Sciences in 1884, and of American linguistics and archaeology in the University of Pennsylvania in 1886. In 1894 he was president of the American Association for the Advancement of Science. His chief works are *The Myths of the New World* (1868; 3d ed., 1896); *The Religious*

Sentiment (1876), *American Hero Myths* (1882), *Races and Peoples* (1890, 2d ed, 1901), *The American Race* (1892), *Religions of Primitive Peoples* (1897), *The Basis of Social Relations* (1902). Perhaps his richest contribution to anthropology was his *Library of Aboriginal American Literature* (8 vols, 1882-85), designed to "put within reach of scholars authentic materials for the study of the languages and culture of the native races of America." Just before his death he gave his entire library of books and manuscripts to the University of Pennsylvania.

BRINTON, JOHN HILL (1832-1907). An American surgeon. He was born in Philadelphia and graduated at the University of Pennsylvania and the Jefferson Medical College. At the outbreak of the Civil War he volunteered his services and remained in the army until 1865, attaining the position of brigade surgeon. He was connected with many hospitals in Philadelphia. In 1882 he was appointed professor of the practice of surgery and of clinical surgery in the Jefferson Medical College.

BRINVILLIERS, brān'vél'ya, MARIE MADELINE MARGUERITE, MARQUISE DE (c 1630-76). A French woman notorious as a poisoner. She was born about 1630 and married in 1651 the Marquis de Brinvilliers. Incensed at her scandalous life, her father caused her lover, Sainte-Croix, to be thrown into the Bastille. There Sainte-Croix learned of an Italian named Exili the art of compounding poisons, and when free imparted the secret to his mistress, Brinvilliers. Brinvilliers poisoned her father, her two brothers, and her sister, and attempted to poison her husband. But Sainte-Croix, not over-anxious to succeed to the latter's place, supplied him with antidotes. In 1672 Sainte-Croix died, poisoned by accident, his death led to an investigation that revealed the enormity of Brinvilliers' crimes. The Marquise fled, but was captured and executed, July, 1676. Brinvilliers seemed a woman of great piety, attended church regularly, and once, espousing the cause of a poor girl, poisoned a whole family. Her exposure soon led to the discovery of the famous poisoner La Voisin (qv). Consult *Pirot, La Marquise de Brinvilliers* (Paris, 1893). See also CHAMBERE ARDENTE.

BRINZ, brēntz, ALOYS VON (1820-87). A German jurist and legislator. He was born at Weier, Bavaria, and studied philology and law in Munich and Berlin. He was professor of Roman law at the universities of Erlangen, Prague, Tübingen, and Munich. In 1861 he was elected to the Imperial Council of Austria and became one of the chief defenders of the German interests in Bohemia. His principal work is the *Lehrbuch der Pandekten* (2 vols, 1857-71, 3d ed., 1884), and other important contributions to the literature of jurisprudence are the following: *Zum Rechte der Bonae Fidei Possessio* (1875), *Zur Contraindicatio* (1877), *Zum Begräff und Wesen des römischen Procurator* (1885), *Ueber den Einlassungswang in Römischen Recht* (1887).

BRION, brē-ōn', Fr pron brē-ōn', FRIEDRIKE ELISABETH (1752-1813). One of the most famous of Goethe's sweethearts, born at Niederrodern (Alsace), better known, from her place of residence near Strassburg, as Friederike von Sessenheim, and a prominent figure in Goethe's *Dichtung und Wahrheit*. (See GOETHE.) She inspired many of Goethe's early lyrics and has been

declared the original of Maria in *Goiz von Belshungen* as well as of Gretchen in *Faust*. Consult Duntzer, *Friederike von Sessenheim in Lichte der Wahrheit* (Stuttgart, 1893), and A. Bielschowsky, *Friederike und Lili* (Munich, 1906).

BRION, GUSTAVE (1824-77). A French genre painter. He was born in Rothau in the Vosges Mountains and studied at Strassburg with Gabriel Guerin and the sculptor Andreas Friedrich. He is the painter par excellence of the life and customs of his Alsatian home, which he depicts with an art more distinguished by literary than by technical qualities. Among his best paintings are "The End of the Deluge" (Louvre) and "The Potato Harvest during the Inundation" (Nantes); he is well represented in the museums of Strassburg and Colmar. He is also well known for illustrations, those of Victor Hugo's *Les Misérables* deserving of special admiration for the way in which they reproduce the spirit of the work and of modern life.

BRION, brē-ōn', LUIS (1782-1821). A Colombian naval officer. He was born in Curaçao, was educated in Holland, served in the Dutch army, and studied navigation in the United States. With the backing of a large inherited fortune, he engaged successfully in a shipping and mercantile business, but, at the outbreak of the War of Independence, joined the revolutionists. Having fitted out a fleet of ships at his own expense, he cooperated with Bolívar, defeated the Spanish on the island of Margarita, and distinguished himself in the conquest of Guiana. He sat in the Congress of Angostura, which proclaimed the independence of Colombia.

BRIOSCHI, brē-ō'skē, FRANCESCO (1824-97). An Italian mathematician, born and died in Milan. Taking the doctorate at the University of Pavia in 1845, he became professor of applied mathematics in the same university in 1852 and in 1862 was commissioned by the government to found and organize the Istituto Tecnico Superiore at Milan. Together with Tortolini he founded in 1858 the *Annali di Matematica*, which he edited until his death. One of the great mathematicians of his time, he contributed especially to the development of the theories of invariants, equations (especially those of the fifth and sixth degrees), and elliptic functions. Among his distinguished pupils were Cremona, Beltrami, and Casorati. His Works were published in 5 vols (Milan, 1902-09). Consult his biography by Noether, *Mathematische Annalen*, vol. 1, pp 477-491 (1898).

BRIOSCO, brē-ōs'kō, ANDREA (1470-1532). See RICCIO, ANDREA.

BRIQUETTE. See CEMENT, FUEL.

BRISBANE, briz'hān (named in honor of Sir Thomas Brisbane). A seaport, the capital of Queensland, Australia, about 500 miles north of Sydney, situated 25 miles from the mouth of the Brisbane River (Map Queensland, H 9). Regular steam communication is kept up with European and Australian ports. Several railroads terminate here. The Victoria steel bridge, 1040 feet in length, spans the river. A prior bridge and nearly half of South Brisbane were destroyed by flood in 1893. South Brisbane became a separate municipality in 1883 and a city in 1903. Brisbane is the seat of a United States consular agency, the see of Anglican and Catholic bishops, and has two cathedrals, numerous churches, banks, and newspapers, four parks, a museum, a school of arts, and a university. The principal industries are boot factories, soap

works, breweries, tanneries, etc. Brisbane dates from a penal colony established in 1825 and abandoned in 1839. Its growth began in 1842 with the advent of free settlers, and in 1859 it was made the capital of Queensland. Pop., 1901, 28,953; within a 10-mile radius, 119,428; 1911, 141,342.

BRISBANE, briz'bān, ARTHUR (1864-). An American newspaper editor, born in Buffalo, N. Y., and educated in the public schools of this country and in Europe. He began newspaper work (1882) in New York City as a reporter for the *Sun*, later becoming that paper's London correspondent. Following this period he was editor of the *Evening Sun* and then managing editor of the *World* for seven years. In 1897 he accepted the editorship of the New York *Evening Journal*. The immense combined circulation of this paper and the others in the Hearst "chain" throughout the country made Brisbane's opportunity for wide influence as an editor unmatched in the United States. By one part of the community Brisbane is considered a maker of pernicious, if effective, appeals to popular passion and prejudice; by another he is looked upon as a sort of lay preacher of all that is beneficent. However one may regard the content of his writing, it cannot be denied that his direct and forceful style has influenced the form of contemporary American editorials. He was a special lecturer before the School of Journalism of Columbia University in 1913. Some of his writings were collected in 1906 under the title *Editorials from the Hearst Newspapers* and in 1908 he published *My Buler Glover Eddy*.

BRISBANE, SIR THOMAS MAKDOUGALL (1773-1860). A British general and astronomer. He was born at Brisbane, the hereditary seat of his family, near Largs, Ayrshire, July 23, 1773. At the age of 16 he entered the army as an ensign, and in the following year, when quartered in Ireland, became intimate with Arthur Wellesley, afterward Duke of Wellington. With a company that he raised in Glasgow in 1793, Brisbane took part in all the engagements of the campaign in Flanders. Sent to the West Indies in 1795, he distinguished himself under Sir Ralph Abercromby, and in 1812, under the Duke of Wellington, in Spain. Appointed Governor of New South Wales in 1821, he introduced many reforms, especially in penal treatment, and promoted horse breeding and the cultivation of sugar cane, the vine, and tobacco. Immigration began during his administration, but he unwisely gave so much power to the immigrants that great financial confusion resulted, and he was recalled at the end of 1825. The town of Brisbane was named after him, also the river on which it stands. As a man of science Brisbane holds a higher place than as an administrator. While in Australia he made a catalogue of 7385 stars, which is known as the *Brisbane Catalogue*, and for which he received the gold medal of the Astronomical Society. On his return to Scotland he had an astronomical observatory established at his residence at Makerstoun and devoted himself entirely to scientific pursuits. He entered warmly into the plans of the British Association for ascertaining the laws of the earth's magnetism and in 1841 had a magnetic observatory erected at Makerstoun, the observations made there filling three large volumes. He was made a baronet in 1836, G.C.B. the following year, received from Oxford the

degree of D.C.L., and succeeded Sir Walter Scott as president of the Royal Society of Edinburgh. He died at Largs, Jan. 27, 1860.

BRISÉ. See BRIZURE.

BRISÉ'IS (Gk. *Βρισηΐς*, *Brisēis*). In Homer's *Iliad*, the daughter of Briseus and the captive of Achilles. When Agamemnon was obliged to surrender Chryseis (q.v.) to her father, he took Briseis from Achilles (q.v.), thus causing Achilles to withdraw from the fight against Troy, and paving the way for all the events of the *Iliad*.

BRISIACUS MONS. See BREISACH.

BRISSAC, bré'shak', CHARLES DE COSSÉ, COUNT OF (1505-63). A marshal of France. He fought against the English and the Imperial troops in 1544-46 and was made a marshal in 1550. In 1559 he became Governor of Picardy, and in 1563 of Normandy.

BRISSON, bré'sōn', BARNABÉ (Lat. *Brissoniensis*) (1531-91). A French jurist and diplomat, born at Fontenay-le-Comte, of a distinguished family. Brisson chose the legal career, and rapidly advanced in his profession. In 1575 he became King's Advocate, later Counselor of State, and in 1583 president of a provincial tribunal. He was dispatched on a diplomatic mission to England to arrange a marriage between Elizabeth and the Duke of Anjou; and thereafter he was frequently sent as envoy to foreign countries. In 1588, when King Henry III was obliged to flee from Paris, Brisson remained behind, apparently in the hope of reconciling the King and the people. After the King's death in August, 1589, Brisson resisted the intrigues of the Spanish ambassador and the claims of the papal envoy and had the Duke of Mayenne proclaimed lieutenant general of the kingdom. He unfortunately fell under suspicion of favoring Henry IV and, at the orders of the Council of Sixteen, was arrested and hanged, Nov. 15, 1591. Brisson was a man of remarkable judgment and learning and was held in such esteem by Henry III that that monarch declared no king had in his service so learned a man as he. His literary works were numerous; the most important are the following: *De Verborum Quæ Ad Jus Pertinent Significatione*, etc. (1557); *Observationum Divini Et Humani Juris Liber* (1564); *De Formulæ Et Solennibus Populi Romani Verbis*, etc. (1583), a work of great value not yet superseded, last edited by Conrad (1781); *Code de Henri III* (1587); *Nota in Titum Livium* (1588); *Opera Minora*, chiefly on Roman law and institutions (1606), etc. Consult Le Bas, *Dictionnaire encyclopédique de la France*, vol. iii (Paris, 1835-63).

BRISSON, EUGÈNE HENRI (1835-1912). A French statesman. He began the practice of law in 1859, but engaged also in journalism, and in 1868, together with Challemeil-Lacour and Allain-Targé, established the *Revue politique*. He was elected to the National Assembly as a Republican in 1871 and soon submitted a proposition of amnesty for all political offenders. He became President of the Chamber of Deputies in 1881, was the head of the French cabinet in 1885 (April to December), was again chosen President of the Chamber of Deputies in 1894, and was once more head of the ministry from June to October, 1898, his fall being due to the consent of the ministry to a revision of the Dreyfus case. In the election for President of the Republic, Jan. 17, 1895, he received 361 votes to 430 for Félix Faure. He was chosen President

of the Chamber of Deputies in January, 1904, but failed of reelection in the following year owing to a combination of forces hostile to the Combes ministry. He became President again, June, 1906, receiving 500 of 581 votes in the Chamber. He wrote *La congrégation, aperçu historique* (1902), *Souvenirs, Affaire Dreyfus* (1908).

BRISSON, MATHURIN JACQUES (1723-1806) A French natural philosopher, born at Fontenay-le-Comte (Vendée). He was instructed by the famous Reaumur and was professor of physics in Paris, successively at the Collège de Navarre, the Ecoles Centrales, and the Lycée Bonaparte. In his own way he was widely known as an ornithologist, particularly through his 6-volume *Ornithologia* (1760, with 500 plates), since quite superseded. His further works include a *Dictionnaire raisonné de physique* (2 vols, 1781, 4 vols, 1800) and *Pesanteur spécifique des corps* (1787).

BRISSET DE WARVILLE, bré'sô' de var-vêl', JEAN PIERRE (1754-93). A French jurist and politician. He was born at Chartres, Jan. 14, 1754. Though his father was a "modest innkeeper," Brisset received a good education and was trained for the bar. Two scholarly works on criminal law, *Théorie des lois criminelles* (1780) and *Bibliothèque des lois criminelles*, published soon after, established his reputation as a jurist. His passion for political studies carried him beyond the narrow bounds of his profession, and, in conjunction with his friends Clavière and Muraubeau, he produced several works on finance. A master of the English language, he attempted to conduct in London a journal entitled *Journal des Lycées*, but, not being successful, returned to Paris. He was imprisoned in the Bastille for four months on a false charge of having written a brochure against the government. Upon his release he again engaged in the writing of pamphlets upon politics and economics, and was compelled to take refuge in England for a time, on account of his fearless expression of opinion upon the condition of affairs in France. In 1788 he founded the Society of the Friends of the Negroes (Société des Amis des Noirs), and visited the United States to study the problems of slavery and emancipation and to promote the abolition of the slave trade. At the outbreak of the Revolution he returned to France and entered actively into political affairs, establishing a journal, *Le Patriote Français*, which at once became the recognized organ of the Republicans. He became the leader of a strong group of young reformers, who were known as Brissotins and who afterward formed the Girondist party. He was frequently consulted by the Constitutional Committee of the Assembly, and in 1791 was elected to that body from Paris, against the opposition of the court party. In the Legislative Assembly his influence upon the foreign policy of France was predominant, and he was responsible for the beginning of the Wars of Revolutionary Propaganda, was also a member of the Convention and used his influence against anarchy and for moderation. He disapproved the execution of the King and urged that the question be submitted to the people. He thus incurred the distrust and hostility of the extreme Jacobins, who came into power in 1793, and was one of the 21 Girondist leaders who were guillotined on October 31 of that year. Consult Brisset, *Mémoires pour servir à l'histoire de la Révolution* (4 vols, Paris, 1830; new

ed. by Leseure, 1877), and Desmoulins, *The History of the Brissotins*, trans. from the French (London, 1794).

BRISTED, CHARLES ASTOR (1820-74). An American author, son of the Rev. John Bristed and grandson of John Jacob Astor. He was born in New York and was educated at Yale and at Trinity College, Cambridge, England. For several years he was contributor to periodical literature under the signature "Carl Benson." He was one of the first board of trustees of the Astor Library. Among his collected works are *The Upper Ten Thousand of New York* (1852), *Five Years in an English University* (1852), *The Concord Convention* (1864), *The Interference Theory of Government* (1867), and *Letters to Horace Mann* (1850), in which he replied to attacks upon John Jacob Astor and Stephen Girard.

BRISTLE BIRD. An Australian wren-like bird of the genus *Sphenura*, having two or three pairs of strong, recurved bristles at the angles of the mouth. Three species are known in southern and western Australia. "They mostly conceal themselves in thickets, especially in marshy places, flying very little, but running very quickly, and carrying the tail erect. The nest is built of dry grass, globular in form, and is of large size."

BRISTLES (dim. of *brust*, a bristle, of Ger. *Burste*, brush). The strong hairs growing on the back, and to a less extent on the sides, of the hog, wild boar, and some other animals, and extensively used in the manufacture of brushes and also by shoemakers and saddlers. The quality of bristles depends on the length, stiffness, color, and straightness, white being the most valuable. The best bristles are produced by pigs that inhabit cold countries. The Russian hog is a long, lean animal, and the thinner the hog the longer and stiffer the bristles. When the Russian hog is sent to the south and fattened, the bristles become soft and of course depreciate in value. In the summer the hogs are driven in herds through the forests, to feed on soft roots, etc., when they shed their bristles by rubbing against the trees. The bristles are then collected, sewed up in horse or ox hides, and find their way, through agents, to all countries. While the best bristles come from Russia, China with a somewhat inferior product is also a leading source and supplies from 60 to 75 per cent of all the bristles used for paint brushes in the United States. In American slaughterhouses the bristles of the slaughtered hogs constitute one of the by-products, but those from the modern hog, which is comparatively small and immature when slaughtered, are short and inferior in quality. In 1913 the imports of bristles into the United States amounted to 3,578,584 pounds and were valued at \$3,504,563. See BRUSH and BROOM.

BRISTLETAIL. Any small wingless insect of the order Thysanura, regarded as the simplest and lowest of all true insects. It dwells in dark, damp places, under bark, stones, etc., and sometimes infests the kitchens of untidy houses or the woodwork of bakeshops. In the same order are the springtails and podurids. The bristle-tails, or "silver fish" (*Lepisma*), are swift, agile creatures, having flat, fish-shaped bodies, covered with silvery scales, long, thread-like antennae, and two or more caudal filaments. They will destroy upholstery, bound books, etc., if neglected.

BRISTOE STATION. See BRISTOW STATION.
BRISTOL (ME. *Bristowe*, AS. *Briegstow*, the place at the bridge). An important maritime city and municipal, county, and parliamentary borough in southwest England, situated at the junction of the rivers Frome and Avon, chiefly in Gloucestershire and partly in Somersetshire, 118 miles west of London. It is 8 miles from the confluence of the Avon with the Severn estuary and about 11 miles northwest of Bath (Map: England, D 5).

The original town was composed of the territory bounded by the two rivers, but it has been extended from time to time, so that it now includes Clifton, Redcliffe, Horfield, Staple-ton, St. Thomas, St. George, etc. The area of the county borough is 17,460 acres. Bristol is remarkable for its specimens of mediæval architecture, chiefly ecclesiastical. The cathedral, formerly an Augustinian church (1148), has little to commend it but its handsome Norman chapter house, the Early English north aisle of the choir known as the Berkeley Chapel, and the Norman west portal. Some remains exist of the ancient castle, built probably by Geoffrey, Bishop of Coutances, and improved by Robert, Earl of Gloucester, in the early part of the twelfth century. St. James's Church (1130) is a good specimen of Norman architecture, and other noted churches are St. Philip's, St. Stephen's, All Hallows, St. John's, the Mayor's Chapel, and the Temple Church, but more famous than these, perhaps, is the fourteenth-century church of St. Mary Redcliffe, which is notable for its symmetrical proportions and richness of design. Its tower, more than 200 feet high, was partly destroyed by lightning in 1445, but was rebuilt in 1872. Many interesting old houses are to be found in the Pithay and Maryleport Street. Clifton, the best known of Bristol's suburbs, is a favorite place of its wealthy residents. The suspension bridge over the Avon was, at the date of construction (begun in 1836), one of the largest in the world, having a centre span of 676 feet. The floating harbor and quays are very extensive and are formed by embanking and locking the old courses of the Avon, for which a new channel was cut (1800). In 1884 the city bought the Avonmouth and Portishead docks at the mouth of the Avon. A new dock, the Royal Edward, was opened at Avonmouth in 1908. "The Float," at Bristol, has an area of 85 acres and a depth of 22 feet; the water area of the Royal Edward is 30 acres and its depth at low tide 36 feet. Portishead dock covers 12 acres. The city is one of the most important ports in Great Britain, and its trade is of long standing. In the fourteenth century it had a large trade in cloths, leather, wine, and salt, and was one of the "staple towns." It was prominent in the early commercial ventures and in discovery. It is the port from which John Cabot sailed in 1497 upon the voyage which resulted in the rediscovery of the mainland of America. Bristol traders colonized Newfoundland and engaged largely in the commerce with the West Indies and the American Colonies. Shipbuilding has been a prominent industry there for many years. The *Great Western*, the pioneer in steam communication across the Atlantic (1838), was built at Bristol. The principal imports are cattle, oils, hides, petroleum, grain, tallow, and sugar; the exports are iron, copper, tin plate, coal, salt, cotton goods, earthenware, chemicals, and other manu-

factured products. In the foreign trade the total net tonnage entered in 1911 was 1,049,507, and cleared 817,398; total net tonnage arrived and departed, foreign and coastwise, 5,801,327. Total imports and exports in 1911 were valued at £15,557,506 and £4,016,936, respectively.

Bristol returns four members to Parliament. The city's affairs are administered by a lord mayor, a municipal council, and a board of aldermen. (See GREAT BRITAIN, *Local Government*.) The streets, which are mostly paved with wood or asphalt, are kept in excellent condition by the city's public-works department. Bristol owns and operates an electric light plant. The city maintains public baths and washhouses, charging a nominal price for their use, placing them within reach of the poorer classes of the people. There are numerous parks and pleasure grounds. Among its educational institutions are, in addition to its public schools, University College (1876), the nucleus of the University of Bristol (chartered 1909); Clifton College (1862), the ancient grammar school (1532), the technical college of the Company of Merchant Venturers (1885), a municipal library (with branch establishments), several museums, a zoological and a botanical garden, and an observatory. It has numerous benevolent and charitable institutions, the Queen Elizabeth Hospital, the Muller Orphanage, a sailors' home, a blind asylum, and several hospitals, including two municipal isolation hospitals. Bristol is the seat of an American consulate. Bristol was the seventh English city in size at the census of 1911, when the population of the county borough was 357,048, as compared with 339,042 in 1901, showing a gain of 5.3 per cent.

The city existed before the Roman invasion, but does not come into prominent notice until 1069, when Harold's three sons, in an attempt to regain their patrimony from William the Conqueror, sailed up the Avon, but were defeated under the walls of Bristol. Henry II gave the city its charter in 1171, and it received the rights of a county from Edward III. During the Civil War Bristol was alternately held by Royalists and Parliamentarians. The castle and fortifications were destroyed in 1655 by Cromwell's orders. A notable rising of the populace occurred in 1793 over the imposition of a bridge toll beyond the time fixed for its discontinuance, and the "Bristol Revolution" in 1831, during the Reform Bill agitation, resulted in the destruction of the bishop's palace, customhouse, and other public and private buildings, and in the loss of several lives. Among other celebrities born or connected with Bristol are William of Worcester, the poets Chatterton and Southey, the artist Laurence, Sydney Smith, Coleridge, and Hannah More.

the Cabots" in *Royal Society of Canada, Transactions*, 2d series, vol. III (1897)

BRISTOL A city in Hartford Co., Conn., 18 miles west-southwest of Hartford, on the New York, New Haven, and Hartford Railroad (Map Connecticut, D 3) It has a public library and manufactures clocks, brass goods, tableware, knit goods, tools, etc. Bristol was incorporated in 1785, as a borough in 1803, and as a city in 1911 It adopted the commission form of government in 1911 Pop., 1900, 6268. 1910, 13,502 Consult Trumbull, *Memoir History of Hartford County* (Boston, 1886)

BRISTOL A borough in Bucks Co., Pa., 23 miles by rail northeast of Philadelphia, opposite Burlington, N. J., on the Delaware River, the Delaware and Lehigh Canal, and the Pennsylvania Railroad (Map Pennsylvania, M 7) It has a foundry, worsted, steel, and planing mills, and manufactures leather goods, carpets, cast-iron pipe, and wall paper Bristol, originally called Buckingham, was settled in 1681 A detachment of the American army was stationed here during part of the Revolution It was first incorporated in 1720, and the charter of that year, as revised in 1905, is now in operation The burgess holds office for four years, and the power of appointments is vested with the borough council The water works are owned by the borough Pop., 1900, 7104, 1910, 9256

BRISTOL A borough, port of entry, and the county seat of Bristol Co., R. I., 15 miles south by east of Providence, on Narragansett Bay, on the New York, New Haven, and Hartford Railroad and on the line of the Providence and New York Steamship Co. (Map Rhode Island, C 3) It contains a State Soldiers' Home, Benjamin Church Home for Aged Men, Old Ladies' Home, Children's Home, and a fine public library Bristol has an excellent harbor, and the principal industries are boat building and the manufacture of rubber, woolen, and cotton goods Pop., 1890, 5478, 1900, 6901, 1910, 8565

Many antiquarians believe that it was at or near the present Bristol that the Northmen, in the year 1000 and subsequently, built the dwellings mentioned in the Icelandic Sagas Within the limits of the present town the Narragansett village Mount Hope, the residence of Massasoit and King Philip, was located, and it was near here that the latter was killed in 1676 Bristol was first settled by the whites in 1680 and was incorporated as a town in 1746 In 1775 and in 1778 the English entered the town and did considerable damage In 1873 a portion of the township was annexed to Warren Consult Munro, *History of Bristol* (Providence, 1880), and Miller, *Celebration of the Two-Hundredth Anniversary of the Settlement of the Town of Bristol* (Providence, 1881)

BRISTOL A city in Sullivan Co., Tenn., and in Washington Co., Va. (the boundary line of the two States running through the principal street), 131 miles from Knoxville, on the Southern, the Virginia and Southwestern, the Norfolk and Western, and the Holston Valley railroads, and on Indian River (Map Virginia, B 5) It is important as a railway center and has extensive lumber and pulp mills, a coffin and casket factory, a tannery, foundries, a sheet-metal factory, a brick plant, and manufactories of metal polish and cleansers, stoves, buggies, wagons, and mine car wheels. The educational institutions include King College (Presbyterian), organized 1867, Sullins College (Methodist Epis-

copal, South), and Southwest Virginia Institute (Baptist), for women, established 1869 and 1884, respectively, and a normal college for negroes Settled in 1851, Bristol was incorporated the following year Bristol, Tenn., has adopted the commission form of government Bristol, Va., is governed by a mayor and council, elected every two years There are municipal water works Pop., 1910, 13,395 (7148 in Tennessee and 6297 in Virginia)

BRISTOL, CHARLES LAWRENCE (1859-) An American biologist, born at Ballston Spa, N. Y. He graduated from New York University, was instructor in science at River-view Academy in 1884-87, professor of zoology at the University of South Dakota in 1887-91, and after further graduate study at Clark University and the University of Chicago, became in 1894 professor of biology at New York University Professor Bristol directed several zoological expeditions to Bermuda and had charge of the transportation of live tropical marine animals to the New York Aquarium His publications include *The Metamorphosis of Nephelis* (1899) and "Treasures of the New York Aquarium" in the *Century Magazine* (1899)

BRISTOL BAY A shallow eastern arm of Bering Sea, north of the peninsula of Alaska (Map Alaska, F 7)

BRISTOL BOARD A thick, stiff paper or fine pasteboard, made with a smooth and sometimes with a glazed surface It was first made at Bristol, England, and is used by artists and draughtsmen

BRISTOL BRICK, or **BATH BRICK** A substance composed of fine-grit sand and used mainly for cleaning and polishing table cutlery and other bright steel surfaces It was formerly made only in Bristol, England, but is now produced in the United States

BRISTOL CHANNEL The largest inlet of the Atlantic Ocean in England, on the southwest coast, between South Wales and Monmouthshire on the north, and the counties of Devon and Somerset on the south, prolonged at its east end by the estuary of the Severn (Map England, B 5) It is about 80 miles long and 5 to 48 miles broad, the greatest breadth being between St Gowan's Head and Hartland Point It has an irregular coast line of 220 miles and receives a drainage of 11,000 square miles The chief rivers which flow into it are the Towy, Taft, Usk, Wye, Severn, Avon, Axe, Parrott, Taw, and Torridge The tides rise to an extraordinary height—at Bristol, 35 feet, at King's Road, 40 feet, and at Chepstow, a rise of 47 feet has been recorded Large ocean vessels can ascend the channel to the heart of the city of Bristol, which is nearer to London than either Liverpool or Southampton

BRISTOL, EARL OF See DIGBY, GEORGE

BRISTOW, BRISTO, BENJAMIN HELM (1832-96) An American lawyer and politician He was born in Elkton, Ky., graduated at Jefferson College, Pa., in 1851, and practiced law in his native State until the beginning of the Civil War, when he volunteered for service in the Union army and soon rose to the rank of colonel He was appointed United States Solicitor-General in 1870 and was nominated as Attorney-General of the United States in 1873, but was not confirmed From 1874 to 1876 he was Secretary of the Treasury, and in this office was active in the prosecution of the "Whisky Ring" (q v.).

This gave him a reputation as a reformer, and at the Republican National Convention of 1876 he received 113 votes on the first ballot for presidential candidate. In that year he removed to New York, where until his death he had a large legal practice. Consult D. Wilcox, *Memorial of Benjamin Helm Bristow* (Cambridge, 1897).

BRISTOW, GEORGE FREDERICK (1825-98). An American musician and composer. He was born in Brooklyn, N. Y., became a violinist in the New York Philharmonic Society in 1842; from 1851 to 1862 was conductor of the New York Harmonic Society, and subsequently conducted the Mendelssohn Union. He was also organist in various churches and a teacher of music in the public schools of New York. His works include *Up Van Winkle*, an opera produced in New York in 1855; an overture to an unfinished opera, *Columbus*; an oratorio, *Daniel* (1867); a cantata, *The Great Republic* (1880), with accompaniment for orchestra; five symphonies; two string quartets; and several anthems.

BRISTOW, JOSEPH LITTLE (1861-). An American public official and legislator, born in Wolf Co., Ky., and, after removal to Kansas, educated at Baker University. He held several minor political offices and owned and edited the *Salina* (Kans.) *Daily Republican* for five years, and the *Ottawa Herald* for more than a decade. In 1903 he bought the *Salina Daily Journal*. During two administrations (1897-1905) while fourth assistant Postmaster-General he brought to light the postal frauds in Cuba and carried through many important reforms in his department. President Roosevelt appointed him in 1905 a special commissioner of the Panama Railroad, and in 1909 he was elected to the United States Senate. Senator Bristow identified himself with the progressive wing of the Republican party in 1912, supporting Theodore Roosevelt as candidate for the Republican presidential nomination. He became known as one of the most diligent and effective members of the Senate, serving on many important committees. He was chosen chairman of the joint committee of the House and Senate to investigate the question of the general parcel post.

BRISTOW, or BRISTOE, STATION. A village in Prince William Co., Va., 4 miles southwest of Manassas Junction, on the Southern Railway. On Aug. 28, 1862, during the Civil War, General Jackson, by a sudden movement, captured a large quantity of Federal supplies and munitions of war which had been stored here; but, threatened by an attack of 40,000 Federals under McDowell, he withdrew on the 27th to the Bull Run battle ground. Here, also, on Oct. 14, 1863, the rear guard of General Meade's Federal army, under General Warren, repulsed with great gallantry the attack of a superior Confederate force under Gen. A. P. Hill, each side losing between 300 and 400 in killed and wounded.

BRISTOWE TRAGEDY, THE, or THE DEATH OF SIR CHARLES BADWIN. A narrative poem by Thomas Chatterton.

BREIT, or BRET. 1. The young of the common herring, formerly thought to be a small separate species, living along the New England coast. The term is frequently applied to the small fry of various other marine fishes. 2. A sailor's term for the food of the whalebone whale, which consists of entomostracans, ptero-

pods, and various other small surface-swimming animals.

BRITAIN. See BRITANNIA; GREAT BRITAIN. **BRITANNIA** (Lat., Gk. *Bperraria*, *Brettania*, from *Bperrai*, *Brettanoi*, Britons). The ancient name of England and Scotland. (See BRITANNICE INSULÆ.) Julius Caesar invaded Britain twice, in 55 and 54 B.C. In the latter year he subdued Cassivelaunus, who agreed to pay tribute; but as no Roman garrison was left, the island remained independent. The emperors Augustus, Tiberius, and Caligula maintained friendly relations with its chiefs, as they thought its subjugation would be too difficult. In 43 A.D., under Claudius, the conquest began. The first expedition secured a portion of the island, and from that time, in spite of stubborn resistance, especially by Caractacus and Boadicea, the invasion progressed steadily, and Britain became a Roman province. Agricola, in 78-85 A.D., finished the conquest up to the Firth of Forth and did much to Romanize the inhabitants. The people of the Highlands maintained their independence. In 122 A.D. Hadrian visited Britain and began the construction of the wall, known by his name, from the Tyne to the Solway, some 70 miles in length. Later, in 142 A.D., the wall of Antoninus was built across the narrowest part of the island, from the Firth of Clyde to the Firth of Forth, about 37 miles long. Both of these walls were intended as bases for military operations and were strengthened by numerous military posts. They do not mark the frontiers of the Roman possessions. The subsequent military history of Roman Britain is marked by few events of importance. (See CALEDONIA; CAURAUSIUS; PICTS; SEVERUS, SEPTIMIUS.) The Roman legions were withdrawn in 409 A.D., and Britain soon became the prey of invaders. See ANGLO-SAXONS.

In the later Empire, according to the *Notitia Dignitatum*, Britain formed a diocese of the prefecture of Gaul and was subdivided into five provinces: Maxima Caesariensis, Valentia, Britannia Prima, Britannia Secunda, and Flavia Caesariensis. The boundaries of these provinces are very uncertain. To insure the obedience of the natives, at least three Roman legions were usually in Britain. Under the Romans many towns (*coloniae* and *municipia*)—56 are enumerated by Ptolemy—arose in Britain and may have been the means of diffusing Roman law and civilization over the country. Among the most important were *Londinium* (London), *Eboracum* (York), *Verulamium* (St. Albans), *Camulodunum* (Colchester), *Durovernum* (Canterbury), *Venta Icenorum* (Norwich), *Aqua Solis* (Bath), and *Lincoln* (Lincoln). The Romans built many roads (*strata*), of which there are still numerous remains. (See WATLING STREET.) They also developed Britannia into a corn-growing country. Dualism was the religion of the Britons at their conquest by the Romans, but the latter introduced Christianity into the country. There are many remains still extant of the presence of the Romans in Britain, such as camps, roads, ruins of houses, baths, fuses, altars, mosaic pavements, painted walls, metallic implements and ornaments, weapons, tools, utensils, pottery, coins, sculptures, bronzes, inscriptions, etc. These remains have been held to show that the Romans sought to render their British conquests permanent, and that they had greatly improved the arts of the ancient Britons, as is evident on comparing the remains with

the far ruder native antiquities of the British pre-Roman or prehistoric era, such as tumuli, barrows, earthworks, so-called Druidical monoliths, and circles, cromlechs, canns, pottery, weapons, tools, utensils and ornaments, etc. But there is great dispute as to the extent to which the Romans had introduced into the country the refinements and luxuries of Rome itself.

Under the term "Britannia," Great Britain has been personified in the fine arts as a female seated on a globe or on an island rock, leaning with one arm on a shield, with the other hand grasping a spear or a trident. The first example of this personification is on a Roman coin of the time of Hadrian. The figure reappears first on the copper coinage of England in the reign of Charles II (1665), the celebrated beauty, Miss Stewart, afterward Duchess of Richmond, is said to have served as a model to the engraver, Philip Roettier. The Britannia that appears on the reverse of British copper coins since 1825 was the design of Mr. W. Wyon (See NUMISMATICS). Among a considerable number of good books on ancient Britain, consult especially Elton, *Origins of English History* (London, 1882), Scarth, *Roman Britain* (London, 1883), Holmes, *Ancient Britain and the Invasions of Caesar* (Oxford, 1907), *The Cambridge Medieval History*, vol. 1, chap. xiii (London and New York, 1911), which gives an excellent bibliography.

BRITANNIA METAL (first manufactured in England, see below). An alloy of tin, antimony, copper, and sometimes zinc. Its composition is adapted to the special uses for which it is intended, the relative amounts of its constituents being as follows: from 81 to 90 parts of tin, from 8 to 16 parts of antimony, from 1 to 2 parts of copper, and sometimes 2 parts of zinc. The alloy may be cast and is malleable, so that it can be rolled into thin sheets. Being harder than pewter, it largely superseded that alloy for many purposes, while its other valuable properties lead to its extensive use for domestic utensils, such as spoons, drinking cups, and teapots. With the introduction of the electroplating processes it found an increased application as a base for plated ware. A brilliant lustre can be given to Britannia metal by heating articles made from it in a bath containing cream of tartar, tartar emetic, hydrochloric acid, powdered zinc, and powdered antimony. By varying the proportions and omitting the zinc, golden, copper-red, violet, and blue-gray tints may be obtained. A metalising has been given to articles made from Britannia metal by heating them in an oil bath to 220° C. Britannia metal was first manufactured in Sheffield, England, by Hancock and Jessop, in 1770. At present Sheffield and Birmingham in England and Connecticut in the United States, are the principal localities of its manufacture. A variety of Britannia metal, consisting of 9 parts of tin and 1 part each of antimony, bismuth, and lead, is called *Queen's metal* and is used for the same purposes as Britannia metal.

BRITANNIA SECUNDA (Lat. second Britain). The Roman name of Wales (qv).

BRITANNIA TUBULAR BRIDGE See BRIDGE.

BRITANNICÆ INSULÆ (Lat. translation of Gk. *Ἰβερνικαὶ νῆσοι*, *Brettanikoi nēsoi*, British Islands). A term used by Greek and Roman authors for the British Isles, including Albion (England and Scotland) and Hibernia,

or Ierne (Ireland), with the adjacent islands. The Phœnicians visited these islands in order to procure tin. Herodotus, in the fifth century B.C., mentions the Tin Islands, but knows nothing definite about them or their location. Aristotle, in the fourth century B.C., is the first to mention them by name, and speaks of only the two, Albion and Ierne. Pytheas of Massilia, a little later, made a voyage to the British Isles, and described them and their inhabitants at considerable length. Julius Cæsar was the first to call Albion "Britannia." Strabo and Diodorus Siculus both speak of Britain at some length. Ptolemy, about 150 A.D., described Ievaina and Albion much more accurately. He located Scotland erroneously, but he gave an excellent account of the coast of England. Consult Tozer, *History of Ancient Geography* (Cambridge, 1897).

BRITANNICUS The son of the Emperor Claudius and Messalina, born Feb. 12, 41 A.D. His real name was Tiberius Claudius Cæsar, but the title *Britannicus*, by which he is known in history, was bestowed by the Senate after Claudius' campaign in Britain in 43. In 48 Messalina was put to death, and Agrippina, who now gained the ascendancy over the Emperor and soon after married him, persuaded him to pass over his own son, Britannicus, and name as his successor her son, Nero (See AGRIPPINA, 2). Fearful that Britannicus might prove a rival, Nero, as Emperor, caused him to be poisoned by Locusta, early in 55.

BRITISH AMERICA The general term applied to the British possessions of North America north of the United States, which thus include Canada and Newfoundland. With a broader meaning British America includes also all British possessions on or adjacent to the American continent, in addition to the above it includes the Bermuda Islands, the British West Indies, and the Falkland Islands.

BRITISH ARMY See GREAT BRITAIN.
BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE See ADVANCEMENT OF SCIENCE, ASSOCIATIONS FOR THE.

BRITISH CENTRAL AFRICA A name formerly applied to the British territory north of the Zambesi River, including the northern part of Rhodesia (qv), and the Nyasaland Protectorate (qv), known from 1893 to 1907 as the British Central Africa Protectorate.

BRITISH CENTRAL AFRICA PROTECTORATE A British colonial possession in Central Africa. See NYASALAND PROTECTORATE.

BRITISH COLUMBIA The third largest province of the Dominion of Canada (Map Canada, E 5), situated on the Pacific coast, between the United States and the Yukon Territory, lat. 49° and 60° N. The southern extension of Alaska forms a narrow strip between its northern half and the sea, as far south as Portland Canal, below which the coast is bordered by the Queen Charlotte and other lesser islands and by the great island of Vancouver (qv). The eastern boundary of the province follows the main divide of the Rocky Mountains north to the 54th parallel, and then conforms with the 120th meridian of west longitude to its intersection with the 60th parallel. Area, about 353,000 square miles. (As the main divide of the Rocky Mountains has not been determined throughout, and part of the boundary of the southern extension of Alaska is still undefined, it is only possible to give the area of the province approximately.)

Topography. Except the northeastern corner, which belongs to the central lowland of North America, British Columbia forms part of that broad mountainous highland belt which accompanies the Pacific side of the continent and is termed the North American Cordillera. Within the province it may be divided into four longitudinal belts, named from east to west as follows: (1) the Rocky Mountain system; (2) the Central Plateau; (3) the Coast Range; and (4) the Island Range. The general trend of all these belts is northwest-southeast. The Cordillera, measured from the central lowland to the Pacific, decreases from a width of about 450 miles on the southern to 350 miles on the northern border of the province.

The Rocky Mountain system is further subdivided into two longitudinal belts by a remarkable trough-like valley, some 900 miles long, termed the Rocky Mountain Trench, which is drained by streams alternately flowing in opposite directions, viz., the middle Kootenay (flowing southeast), the upper Columbia (northwest), the Canoe (southeast), the upper Fraser (northwest), the Parsnip (northwest), the Finlay (southeast), and Kachika (northwest) rivers. To the northeast of this trench lie the Rocky Mountains proper, to the southwest the remaining members of the system. These are distinctly developed only in the southern part of the province. Three ranges may be distinguished, which are separated by secondary longitudinal trenches. From east to west these are: (1) the Purcell Range, bounded on the west by Kootenay Lake and the Duncan River; (2) the Selkirk Mountains, bounded on the west by the south-flowing section of the Columbia River and its expansion, Upper and Lower Arrow Lakes; and (3) the Gold Range, which is bounded on the west by the plateau region. These three ranges are distinct in structure from the Rocky Mountains proper. To the north a fourth range may be distinguished, the Cariboo Mountains, paralleling the left bank of the northwest-flowing section of the Fraser River.

Of the Rocky Mountains proper only the western slope south of lat. 54° belongs to the province. On the whole they decrease in elevation from the south, where many peaks attain 10,000 feet elevation or more, to the north, where the mean altitude drops to 5000 feet near the Liard River, which may be considered to be their northern limit as a distinct range. They culminate in the region of the headwaters of the North Saskatchewan and Athabasca rivers, where, near the former, Mount Bryce attains about 13,000 feet altitude, and, near the latter, Mount Robson, the highest known peak in British Columbia, has, by triangulation, an elevation of 13,068 feet. The range is crossed in its entire width by the transverse valley of the Peace River in 56° N. (2000-1800 feet), and numerous relatively low gaps afford easy passage from one side to the other. Among these the most important are the Crow's Nest Pass in lat. 49° 30' (4449 feet), followed by a branch of the Canadian Pacific Railway; the Kicking Horse Pass in lat. 51° 30' (5320 feet), followed by the transcontinental line of the same railroad; and the Yellowhead Pass in lat. 53° (3738 feet), followed by the transcontinental line of the Grand Trunk Pacific Railway. Of the three ranges constituting the remainder of the Rocky Mountain system, as

here defined, the Selkirk Mountains are by far the most conspicuous. Their rock composition, which consists mainly of schists and quartzites, coupled with the greater glaciation due to the heavier precipitation from the prevailing westerly winds, has given them a far more alpine appearance than the Rocky Mountains with their layers of limestones and shales whose disintegration gives them a castellated or crinellated appearance. If the designation be justified, the Selkirk Mountains, more than any others, deserve to be called the "Switzerland of America." The highest part of the range lies to the north, where many peaks exceed 10,000 feet in altitude. In the vicinity of the Canadian Pacific Railway, which crosses the Selkirks by Rogers Pass (4351 feet), lie Mount Sir Donald (10,808 feet) and Mount Dawson (11,113 feet). To the north, within the "Big Bend" of the Columbia River, lies the highest known peak of the system, Mount Sir Sandford (11,634 feet). Of the explored glaciers, Illecillewaet Glacier is the best known, Sir Sandford Glacier the longest (7 miles).

The other two ranges—the Purcell Range to the east, and the Gold Range to the west of the Selkirk Mountains—are similar to them in structure, although of lesser elevation. In the former, however, Mount Nelson (lat. 50° 24') attains 10,000 feet; the highest peak in the Gold Range, Joss Mountain, is only 7900 feet high.

Between the subdivisions of the Rocky Mountain system the Columbia River follows a rather remarkable course. Rising in lat. 50° 12' in Upper Columbia Lake, within a mile of whose upper end, and separated from it only by a low gravelly flat, flows the Kootenay River, the Columbia flows northwest, as stated above, in the Rocky Mountain Trench to a little beyond lat. 52°, where it turns abruptly south, or even southeast, forming an acute angle with its upper course, and flows between the Selkirk Mountains and the Gold Range out beyond the limits of the province.

Between the Rocky Mountain system on the east and the Coast Range on the west lies the Central Plateau. A series of longitudinal ranges in lat. 55° and 56° (Babine Range, Firepan and Omineca Mountains) divide this district into two parts, a northern and a southern. The former, which consists mainly of the basin of the Stikine River, is quite rugged, being interrupted in its plateau character by several mountain ranges, notably by the Cassiar Mountains. The southern part, which is specifically known as the Interior Plateau of British Columbia, has a mean elevation, at its plateau surface, of 3500 feet. Into this the main rivers have eroded deep valleys. The most important of these is the Fraser, which, rising in Yellowhead Pass, first flows northwest in the Rocky Mountain Trench and then turns abruptly, repeating on a larger scale the behavior of the Columbia, flows south diagonally across the Interior Plateau, and finally issues into the sea after having rounded the southern end of the Coast Range. A typical feature of the Interior Plateau is the large number of lakes which dot its surface. Chief among these are, in the north, Tlacla, Babine, and Stuart lakes; in the centre, Quessnel Lake; and, in the south, Adams, Kamloops, Shuswap, and Okanagan lakes. The Interior Plateau is characterized by the absence of forest; it is a prairie region of a considerable degree of aridity.

The Coast Range rises like a mighty wall which shuts off the interior of the province from the sea. It extends for at least 800 miles from the lower course of the Fraser on the south to Lynn Canal in the north, beyond which it may be considered to lie on the inland side of the St. Elias Range. Its peaks average 7000 to 8000 feet in altitude, in the south Mount Alford is the highest peak (8450 feet), in the north, Kate's Needle (9064 feet) in lat. 57°. The chain is crossed through its entire width by the Taku, Stikine, Nass, and Skeena rivers. On its ocean side the Coast Range is deeply indented by numerous fiords, which owe their origin to the same causes as those of Norway, with which country, indeed, this western margin of British Columbia compares very closely, both in configuration and climate. The direct impingement of the moisture-laden winds from the Pacific makes for very heavy snowfall on the seaward slope. North of Dixon Entrance (54° 30') the western slope is in Alaskan territory, within the stretch of coast belonging to British Columbia the most important fiords are, from south to north, Bute Inlet, Knight Inlet, Bulke Channel, Dean Channel, Douglas Channel, and Observatory Inlet.

The Island Range, the westernmost of the four subdivisions of the Cordillera in British Columbia, consists of Vancouver Island and the Queen Charlotte Islands. These represent the remnants of a longitudinal mountain system which was severed from the mainland by the subsidence of the coast. Vancouver Island, with a length of about 285 miles, a maximum width of about 75 miles, and an area of about 12,400 square miles, nearly touches the mainland in its northern portion, where the dividing straits, Johnstone Strait and Discovery Passage, are only a mile or two wide. The mountain range of which the island consists culminates in the north-central portion in Mount Victoria (7484 feet). In the southern portion Mount Arrowsmith attains nearly 6000 feet. The seaward coast of the island is indented by fiords, though less pronounced than those of the mainland. Nevertheless, Alberni Canal in the south and Quatsino Sound in the north nearly truncate the island. The Queen Charlotte Islands consist of a triangular-shaped archipelago with its base in the north and its apex in the south. It is separated from the mainland by Hecate Strait and from the Alaskan islands by Dixon Entrance. Two main islands compose the group. Graham Island in the north, hollowed out in its centre, as it were, by Masset Inlet, and Moresby Island, whose mountain axis culminates in the San Christoval Mountains, about 4000 feet in altitude.

The only remaining portion of the province to be discussed is its northeastern corner, which does not form part of the North American Cordillera. This district belongs to the great central lowland of the continent. It is mainly a region of open plains gradually merging into the forest region in the north, with a mean elevation of 1300 to 1400 feet. The northern portion, which is not well known, is mainly drained by the Fort Nelson River, a right affluent of the Liard. Farther south the Peace River with its tributaries, the Halfway, and the North and South Pine rivers, drain a territory which has recently been opened up to agricultural development.

Climate and Agriculture. The equable, tem-
Vol. III—50

perate climate which its position on the western margin of the continent in mid-latitudes would insure to British Columbia is strongly modified by the relief of the province. The position of the Coast Range at right angles to the direction of the prevailing winds limits this climate, which is similar to that of western Europe, to a relatively narrow coastal strip, while the general northwest to southeast trend of the relief features of the province makes for a zonal arrangement of the climate in the same direction rather than along the parallels. The prevailing winds come steadily from the west, and reach the land warm with their passage over the vast breadth of the Pacific, whose waters on this coast have a temperature of 52° F. (about the same as on the Irish coast), or 20° warmer than those of the northwestern Atlantic. These warm winds are loaded with moisture. They are chilled by their first contact with the high coast mountains, causing rapid condensation of the moisture and a heavy rainfall, accompanied by liberation of heat. This is more marked at the northern end of the province than in the south. The consequence is an equable rainy climate on the coast, very similar to that of the south of England, the rainfall usually amounting to about 80 inches at Vancouver. It is least copious in the early autumn. At Victoria the mean temperature for January is 37.2° F., for July, 59.6° F., and flowers bloom all the year round in the gardens. At Agassiz, in the lower Fraser valley, the figures are 33° and 63.9°. Relieved of much of their moisture and warmth, lifted up to 8000 or 9000 feet, and cooled and rained by crossing the coast mountains, the west winds are kept at that height by the buoyant currents of warm air rising from the heated valleys, and blow across the great interior plain without interruption, hence over this wide area rain is very infrequent in summer, the snowfall is light in winter, and there result the conditions of drought, treelessness, and extremes of heat and cold, which are characteristic of interior plains everywhere. At Kamloops, about 200 miles from the coast, the annual rainfall hardly amounts to 12 inches, and the thermometer varies from 100° above zero in midsummer to 40° or 50° below zero in midwinter. Agriculture depends upon irrigation, the table-lands are covered with bunch grass, and the climate is like that of Idaho or Alberta. East of these interior valleys, however, stand the Rocky Mountains, whose summits catch the wind and collect from it almost all its remaining moisture. Hence the Gold Range and Selkirk are covered in all their lower slopes with heavy forests, their crests bear hundreds of glaciers, and the snowfall in the passes amounts to 30 feet in depth, and hence, also, the powerful rivers they sustain. Little moisture is left for the easternmost parts of the Rockies, whose climate is comparatively dry, very cold and clear in winter, and whose forests are thin. Similar conditions in the north, with the favorable addition of the chinook, make the Peace River valley not only pleasantly habitable, but clothed with a vegetation much like that of Ontario, and possessed of climatic and agricultural possibilities similar to those of Scotland.

Soils vary, of course, over so wide and diversified a region, but fertility is general. The rich delta of the Fraser is a perennial garden, and vegetables and fruits there reach an extraor-

dinary perfection. In the interior, light, dry soils prevail, which prove highly productive under irrigation and seem particularly rich in the Okanagan and Nicola districts. Arable regions are limited, however, and form a small part of the total area of the province. On the interior plateau the rainfall is insufficient for the growth of crops, and the rivers so generally flow through deep, narrow channels that the irrigable area is very limited. On the coast and elsewhere, where the rainfall is greater, the forest growth is usually so heavy that it requires great expense to clear and maintain land for cultivation. Wheat grows luxuriantly, but the kernel is too soft for milling purposes. Nevertheless, the southern portion of the province contains scattered districts admirably adapted to ranching and agricultural pursuits, and progress has been made in the delta and lower valley of the Fraser River and in the Okanagan district. In the latter region, especially, fruit farming and hop raising are attaining much importance, and the southern plateau and part of the interior are remarkably well adapted to the cultivation of these products, where labor necessary for picking the hops is supplied by the Indian population. In the late nineties the fruit-growing industry of the Fraser valley suffered much from the prevalence of fungous diseases affecting trees and fruit. Considerable market gardening is engaged in by the Chinese in the neighborhood of the larger towns. The pastures of British Columbia are proving valuable. On the Cariboo road (between Soda Creek and Quesnel), there is a plain 150 miles long, and 60 or 80 wide; and between the Thompson and Fraser rivers there is an immense tract of grazing land. The creamery system has been introduced.

Flora and Forests. The flora is distinctly of a northern type, and the forest resources of the province rank next to the mineral wealth in importance. British Columbia probably contains the largest unbroken area of merchantable forests on the continent. The western slopes of the mountains, particularly the coast ranges, are covered with a dense growth of forest trees which attain remarkable proportions. On the eastern slopes the forests are not so dense nor the trees so large, while much of the interior plateau is well-nigh treeless. The lower Fraser country especially is densely wooded. Smaller streams and the numerous inlets and arms of the sea give access to extensive forests all along the coast. Owing to the very limited Pacific coast market, the forest resources have as yet been but little drawn upon. There are over 100 saw mills in the province, and the lumber cut of 1911 aggregated 1,100,000,000 feet. The most abundant and valuable species is the Douglas fir. On the coast it sometimes attains a height of 350 feet. The white cedar is also widely distributed and is extensively used for shingles and for finishing purposes. The yellow cedar is also of great commercial value. The dense forests of spruce and hemlock north of Knight's Inlet afford an almost inexhaustible supply of pulp wood of a superior quality. The precipitous coast streams supply all the power necessary for carrying on the pulp-manufacturing industry, and arrangements have been made looking to its establishment.

Fauna. The animals of British Columbia are those of the Northwest generally. Wapiti remain only along the eastern foothills of the

Rocky Mountains, but moose, black-tailed deer, and caribou are abundant throughout the valleys everywhere, while the bighorn abounds upon the alpine pastures of the Rocky Mountains and the white goat frequents the summits of the Coast Range. Bears, wolves, and wildcats are known everywhere. Fur-bearing animals are numerous, and in the northern part a great trade in the collection of peltries from Indian trappers is still carried on. This province presents more big-game attractions than almost any other part of North America, and excellent game fish abound in all its streams.

Geology. Over large areas the geology of British Columbia has been studied only in a general way, although more detailed studies have been made of the regions of economic interest. In the Rocky Mountains Archæan rocks are represented by granites, gneisses, and schists, which underlie immense thicknesses of Paleozoic strata ranging from the Silurian to the Carboniferous. Jura-Trias beds are found overlying the Paleozoic in places. At the close of the Triassic the first upheaval took place in the Gold Range and in the highlands of Vancouver and Queen Charlotte Islands. Cretaceous rocks are found along the coast and probably also along the upper course of the Skeena and the lower Nechacs rivers. They hold valuable coal deposits where they outcrop on Queen Charlotte and Vancouver islands. Tertiary strata occur in the southwestern coast region. In the interior of British Columbia between the Rocky and Coast ranges there are areas occupied by limestones, quartzites, serpentines, and igneous rocks, the age of which has not been determined. A large part of British Columbia is mineralized, and gold, silver, lead, and copper ores are wrought in numerous localities. Rossland, Kaslo, Yale, Nelson, Slocum, Trail, and New Denver are important centres of mining industry. Auriferous gravels, resulting from the erosive action of glaciers and rivers, are of widespread occurrence and yield considerable quantities of gold.

Mining. Mining is the principal industry of the province. Placer mining for gold was carried on as early as 1858 along the Fraser River and its tributaries. In 1893 the output reached \$3,900,000, a large part being obtained from the northern interior, about the headwaters of the Fraser, called the Cariboo district. The output then diminished, reaching the minimum of \$379,535 in 1893. The introduction of hydraulic methods and machinery produced a revival of the industry, so that in 1905 the product was valued at \$5,902,402, over four-fifths of which was obtained in lode mining, and, in 1912, \$5,205,485. Silver and lead are obtained from the same ores in the southeastern part of the province, and they have consequently had a parallel development. The silver output increased in value from \$73,000 in 1890 to \$1,972,000 in 1905, while the value of the lead for the latter year amounted to \$2,390,000. The silver output in 1912 amounted to \$1,612,737. The mining of copper is of more recent development. This, too, is obtained from the southeastern portion of the province, where extensive operations began about 1890 in the Kootenay district. From \$111,000 in 1890, the value of the output increased to \$5,876,000 in 1905. The output of coal rose from 90,000 tons in 1874 to 1,384,000 tons in 1905, valued at \$4,153,000; production in 1912, 3,221,000 tons. It is mined

chiefly in Vancouver Island. Vast resources of coal exist in the foothills of the Rockies. The total value of the mineral production of British Columbia up to and including 1905 was as follows: gold, \$104,138,000, silver, \$23,689,000, lead, \$14,058,000, copper, \$27,258,000, coal and coke, \$73,787,000, building stone, etc., \$4,560,000, other minerals, \$253,000, total, \$248,643,000. In 1911 the total mineral production was valued at \$23,499,072, in 1912, \$32,440,800, higher than the value produced in any previous year.

Fisheries. The enormous quantities of fish which frequent the coast waters and streams are another important source of wealth to the province. British Columbia, which formerly was second to Nova Scotia alone in the importance of her fisheries, took first place in 1912. The yield of the fisheries amounted to \$104,000 in 1876, \$1,454,000 in 1881, and \$9,850,000 in 1905, in 1911 and 1912 the yield was valued at \$9,163,235 and \$13,677,125, as compared with \$10,119,243 and \$9,367,550 for Nova Scotia. Salmon is the most valuable fish product of British Columbia, and the value of the yield in 1911 was \$6,744,132, or about three-fourths of the total. The salmon fisheries are most extensive along the Fraser River. Restrictions on salmon fishing obtain, but they are insufficient for the best interests of the industry. Seal fishing is not so important as in former years. The catch increased from 9700 in 1898 to 16,400 in 1900, but declined in the following year to 7200 and in 1903 to 3800, in 1911, 4232, valued at \$118,406. Halibut is next in value to salmon (yield, in 1911, \$1,095,315), herring, cod, smelts, and oysters are among the fishery products.

Manufactures. In 1910 there were 651 manufacturing establishments with an invested capital of \$123,027,521, employing 33,312 hands, paying \$17,240,670 in salaries and wages, and a product valued at \$65,204,236. In 1900 there were 392 manufacturing establishments with an invested capital of \$22,901,892, employing 11,464 hands, paying \$5,459,538 in wages, and a product valued at \$19,447,778. In Vancouver and Victoria, the two largest cities, the value of the manufactured products in 1910 as compared with 1900 increased by 202.30 and 50.19 per cent respectively.

Transportation and Commerce. The transportation facilities of British Columbia have not been fully developed. Communication with the East is, however, established by means of the Canadian Pacific Railway, which crosses the province and is connected at two points with the railroad system of the United States. The same company has a branch route from the coast into the Kootenay region, where the short lines and steamboat routes connect the various mining towns. The western division of the Transcontinental Railway was in operation in 1912 from Winnipeg (Manitoba) to points in British Columbia, but connection with its western terminal, Prince Rupert, had not been completed. Eleven branch lines were under construction in 1912. The railway mileage of the province on June 30, 1912, was 1855. Steamers ascend the Fraser as far as Fort Yale, and others run upon its upper waters and on Lake Okanagan, etc., but the interior is dependent for transportation mainly upon stage lines. In 1913 there were 13,000 miles of standard highway and 15,000 miles of trails, serving a rural population estimated at over 200,000.

Owing to the mountainous nature of the province, the construction of roads and trails involves much skill and daring and labor. Telegraph and mail routes penetrate to all civilized parts of the province. The total imports and exports in 1902 were valued at \$10,391,256 and \$18,355,335, in 1912, \$49,345,161 and \$20,272,840.

Government. British Columbia is represented in the Canadian Parliament by three senators and seven members of the House of Commons. The provincial government is administered by a lieutenant governor (appointed by the governor-general of Canada) and the Legislative Assembly (42 members elected for four years). The lieutenant governor is assisted by a ministry, the Executive Council, responsible to the Assembly. Revenue and expenditure in 1910, \$8,874,741 and \$6,549,994, in 1911, \$10,492,892 and \$5,414,825. Net debt (1911), \$1,497,694.

Banks. The clearing-house transactions of Victoria in 1912 amounted to \$183,544,238, and those of Vancouver to \$645,118,887. The province contains post office and government savings banks.

Education. In 1911, of the population five years of age and over (350,745), 314,183 (89.07 per cent) could read and write. There are free public schools, and, differing from most Canadian provinces, they are wholly under secular control. The system comprehends common, graded, and high schools, with a total teaching force of over 1100, in 1911 pupils numbered 45,125. There are also a number of private schools. Expenditure in 1911, \$2,641,522, of which \$715,734 was for education proper. In 1912 the University of British Columbia, a provincial institution, was endowed by the government with 2,000,000 acres and also with a site of 217 acres at Point Grey, near Vancouver. McGill University College of British Columbia, a branch of McGill University of Montreal, has buildings at Vancouver and Victoria. There is a provincial normal school at Vancouver. Ryerson College (Methodist), Latimer Hall (Anglican), and Westminster Hall (Presbyterian) are in affiliation with the University of British Columbia, but their degree-conferring power is restricted to graduates in divinity. Okanagan College (Baptist) is at Summerland.

Religion. The leading religious denominations in 1911 were Church of England, 100,952, Presbyterian, 82,125, Roman Catholic, 68,397, Methodist, 52,132, Lutherans, 19,362, Baptist, 17,228, Oriental religions, 25,808.

Population. The population of British Columbia was 36,247 in 1871, in 1881, 49,450, in 1891, 98,173, in 1901, 178,657, in 1911 (census of June 1), 392,480, the increase in the last decade being 110.68 per cent. Of the total in 1911, persons of English origin numbered 133,186, Scotch, 74,493, Irish, 40,642, other British, 4362, German, 11,380, Italian, 9721, French, 8907, Austro-Hungarian, 7015, Scandinavian, 15,968, Chinese, 19,568, Japanese, 5857, American Indian, 20,134. There were 25,370 unspecified. The increase in Chinese from 1901 to 1911 was 4683 (increase for all Canada, 10,462). Males numbered in 1911, 251,619, females, 140,861, rural population, 183,706, urban, 203,684. Birth rate, in 1911, 14.88, death rate, 9.39.

Victoria, the capital, containing a population of 31,660 in 1911, is situated in the southern extremity of Vancouver Island. Vancouver, the largest city, with 100,401 inhabitants (27,010 in

1901), is situated on the coast of the mainland. Of the other cities, the largest are New Westminster (13,199 in 1911), Nanaimo (8306), Nelson (4476), Prince Rupert (4184).

Indians. The census of 1901 gives the Indian population as follows: West Coast Agency, 2750; Fraser River Agency, 3380; Babine and Upper Skeena Agency, 2783; Williams Lake Agency, 1899; Northwest Coast Agency, 3094; Kootenay Agency, 562; Cowichan Agency, 2020; Kamloops Agency, 2880; Okanagan Agency, 651; Kwawkwewit Agency, 1639; bands not counted, about 2500; making a total of 25,068. The total as returned by the 1911 census was 20,134. The influences of civilization are thought to have arrested the rate of decline, and there is even an increase in some of the tribes. The status of the coast tribes of British Columbia presents a number of contrasts with that of the Indians of the interior plains and regions farther east. Food is more abundant, the climate is milder, and the Indian is more industrious, and consequently famines are almost unknown, although no financial assistance is now given. Many Indians now own comfortable houses. Land is set aside for them, which they are not allowed to sell without permission from the government. They are not obliged, however, to remain on these reservations, but may acquire property elsewhere, and under certain conditions are admitted to the rights of franchise. Acts passed by the Indian chiefs and councillors may be enforced if approved by the government. Their interests are protected by the Indian Department of the Dominion government. The 1901 census returned 6769 as Protestant and 12,628 as Catholic. The Indian schools are conducted on denominational lines.

History. Captain Cook, the famous explorer, visited a part of the coast of British Columbia in 1778, and 10 years later an English settlement was established at Nootka by Capt. John Meares, formerly a Lieutenant in the British navy, though it was almost immediately broken up by the Spanish, who claimed the whole coast as far as the Russian possessions, on the basis of prior discovery. For some time war appeared imminent between England and Spain, but in 1793 the difficulties between the two courts were settled by arbitration, England receiving all the northwest coast from Nootka Sound to the Russian trading posts in Alaska. Meanwhile, in 1792, Capt. George Vancouver (q.v.) circumnavigated the island which bears his name, besides exploring a part of the coast of the mainland; and in 1793 Alexander Mackenzie (q.v.), a partner in the Northwest Company, reached the coast of the present British Columbia after an arduous overland journey from Lake Athabasca. For many years the territory now included within the province formed part of "New Caledonia," throughout which the Northwest Company and later the Hudson's Bay Company (with which the Northwest Company was amalgamated in 1821) carried on trading operations; and in 1843 a fort was built by the Hudson's Bay Company on the site of the present city of Victoria. A considerable portion of the territory at this time was claimed by the United States, on the strength of the Louisiana Purchase, and feeling ran high, giving origin to the campaign cry of "Fifty-four forty or fight." But under Polk the matter was arbitrated.

In 1849 Vancouver Island was erected into a crown colony, though it remained under the vir-

tual control of the company, Sir James Douglas occupying both the position of Governor and that of the company's chief factor. In 1856 an assembly was called, though the island was still only sparsely settled. Gold was discovered in the bed of the Fraser River in 1856, and, settlers having arrived in some numbers, New Caledonia was also organized as a crown colony in 1858 under the name of British Columbia, of which also Douglas acted as Governor for several years. In 1863 an Act was passed by the British Parliament establishing as the boundaries of the colony the Pacific Ocean and the frontier of the Russian territory in North America to the west, the 60th parallel of north latitude to the north, the 120th meridian of longitude and the summit of the Rocky Mountains to the east, and the northern boundary of the United States to the south. The two colonies were united under the name "British Columbia" in 1866, and five years later the new province thus created was admitted into the Confederation of Canada, the Dominion government pledging itself to pay a considerable subsidy to the province and to secure the construction within 10 years of a railroad connecting the seaboard of the province with the main railway system of Canada. The road, however, was not completed until 1885. Soon after its admission into the Dominion British Columbia secured a constitution under which a government was organized similar to those of the other provinces. The southern, southwestern, and northwestern (Klondike) boundaries of British Columbia have at various times formed the subject of considerable controversy between the United States and Great Britain. See OREGON; SAN JUAN BOUNDARY DISPUTE.

The course of political development under Confederation was not at first in accordance with parliamentary or responsible government. Previous to 1903 governmental administration was more or less personal, the premier and his associate ministers not being strictly accountable to the legislature and often at variance in matters of policy. In that year this condition, which had affected the preceding administrations of John Herbert Turner (q.v.), James Dunsmuir (q.v.), and Edward Gawler Prior, was eliminated by the formation of a Conservative government under Mr. (afterward Sir) Richard McBride (q.v.), and the principle and practice of party government have since been accepted. The change was effected during the lieutenant-governorship of Sir Henri Gustave Joly de Lotbinière (q.v.), who was appointed in 1900. The McBride administration has been in office since 1903, and at the close of 1913 was stronger than ever before in public confidence. The most important questions for many years have been: the demand for "better terms," i.e., increased aid from the Dominion treasury; the need of more railways; Asiatic immigration; and the development of the mining, fishing, and agricultural industries. The Conservative and Liberal parties, together with a sprinkling of Socialists and Laborists, have fought their contests mainly on these questions. During the past 10 years the judicial and educational systems have been efficiently organized, the latter including a provincial university at Vancouver, with affiliated colleges. The demand for "better terms" which the administration of Sir Wilfrid Laurier (q.v.) did not meet with satisfaction to the province, reached in 1907 a more advantageous stage by direct appeal to the Secretary of State for the

Colonies in London, with the prospect of ultimate success. In 1912 the Dominion government, then under the Conservative leadership of Robert Laird Borden (qv), promised to appoint a royal commission to investigate the claims of British Columbia in this regard.

Legislative measures prohibiting Asiatic immigration were enacted by Premier McBride, but were disallowed by the Dominion government as conflicting with national and Imperial policy. With regard to the Japanese, the difficulty was in part removed, on Jan. 1, 1901, by the government of that people, which forbade the emigration of its subjects to Canada. A treaty was also arranged between Great Britain and Japan. (See CANADA, History.) Also in 1903 the Dominion government imposed a heavy poll tax on Chinese immigrants. Nevertheless, the people of the province have continued to look upon the presence of Asiatics, including Sikhs and others from India, as obnoxious. Certain measures were admittedly hastened by the pressure of a small but influential Socialist party. Among them were an eight-hour day for miners working underground (1905), and also for smelters (1907). In 1912 an important report by a commission on taxation recommended a general reassessment, with the view of creating an equitable valuation of land and incomes so as to lower the general rate of taxation. In the same year legislation for the construction of 795 miles of railway was introduced. Labor troubles during the last few years have played an important part. The Industrial Workers of the World made a determined attempt in 1912 to establish their organization in the province. Over 150 of their members were turned back at the frontier, but others succeeded in meeting railway men to strike. A riot, which was quickly suppressed, occurred at Vancouver, and scenes of violence in other places were reported. Several offenders were convicted and received severe sentences. Men were brought in to replace the strikers. In 1906 James Dunsman was appointed Lieutenant Governor, and in 1909 he was succeeded by Thomas Wilson Paterson. The loyalty of the people to British connection was manifest in the enthusiastic reception given to the Duke of Connaught (qv), Governor-General of Canada, during his visit (in which he was accompanied by the Duchess of Connaught) to the province in 1912.

BRITISH EAST AFRICA. A geographical, not an administrative, term applied to that portion of eastern Africa included within the sphere of British influence and extending from German East Africa to Abyssinia and the Anglo-Egyptian Sudan, and from the Juba River and the Indian Ocean to the Belgian Congo. See ZANZIBAR, UGANDA, EAST AFRICA PROTECTORATE.

BRITISH ECONOMIC ASSOCIATION. See ROYAL ECONOMIC SOCIETY.

BRITISH EMPIRE. The United Kingdom of Great Britain and Ireland and all other territories subject to the ultimate control of the Parliament at London. The territories outside of the United Kingdom are styled, in general, either colonies or protectorates. The colonies are immediate possessions of the United Kingdom and have laws and institutions essentially British, each being administered by a governor (of varying official designation) appointed by the crown; the protectorates retain the native government, which, however, is supervised or even controlled by a British official, a "resident" or "adviser." This resident has power to restrain all acts on the part of the native authorities deemed hostile to British interests or the welfare of the community and, in the last resort, to assume the government himself. Some of the African protectorates, especially East Africa and Nyassaland, are practically colonies.

The British colonies and protectorates may be classified as follows:

1. Colonies possessing responsible government, now known as self-governing dominions, in which the crown has reserved only the power of disallowing legislation, and the Secretary of State for the Colonies has no control of any public officer except the governor. In all matters affecting the internal welfare of such a colony the governor acts on the advice of ministers who are responsible to the legislature. In accordance with the established principles of British policy regarding the relations of the legislature and the executive, the crown exercises its power of veto only when the interests not merely of a single dominion, but of the Empire as a whole, are involved. The colonies of this class fall constitutionally into two groups: (1) the Dominion of Canada, the Dominion of New Zealand, the Union of South Africa, and Newfoundland, (2) the Commonwealth of Australia and its six component states (the Northern Territory, the Federal Capital Territory, and the Territory of Papua are administered by the Commonwealth).

II. Colonies not possessing responsible government (sometimes known as crown colonies), in which the administration is carried on by public officers under the control of the Secretary of State for the Colonies, and protectorates similarly

controlled. These dependencies comprise: (1) Colonies possessing an elected house of assembly and a nominated legislative council. These colonies are Bahamas, Barbados, and Bermuda. (2) Colonies possessing a partly elected legislative council, the constitution of which does not provide for a majority of official members (i.e., members who are also executive officers of the colony). These colonies are British Guiana and Cyprus. (3) Colonies possessing a partly elected legislative council, the constitution of which provides for a majority of official members. These colonies are Fiji, Jamaica, Leeward Islands, Malta, and Mauritius. (4) Colonies and protectorates possessing a legislative council nominated by the crown (in all the legislative councils in colonies of this class, except British Honduras, the constitution provides for a majority of official members). These colonies and protectorates are British Honduras, Ceylon, East Africa Protectorate, Falkland Islands, Gambia, Gold Coast, Grenada, Hongkong, Nyasaland Protectorate, St. Lucia, St. Vincent, Seychelles, Sierra Leone, Southern Nigeria, Straits Settlements, and Trinidad and Tobago. The legislative councils of Gambia, Sierra Leone, and Southern Nigeria legislate for Gambia Protectorate, Sierra Leone Protectorate, and Southern Nigeria Protectorate respectively. (5) Colonies and protectorates not possessing a legislative council. These are Ashanti (protectorate administered by a chief commissioner under the government of the Gold Coast), Basutoland (protectorate administered by a resident commissioner under the direction of the High Commissioner for South Africa), Bechuanaland Protectorate, Gibraltar, Northern Nigeria, Northern Territories of the Gold Coast (protectorate administered by a chief commissioner under the government of the Gold Coast), St. Helena, Somaliland Protectorate, Swaziland (administered by a resident commissioner under the direction of the High Commissioner for South Africa), Uganda Protectorate, Weihaiwei (leasehold), and islands under the High Commissioner for the western Pacific (including the Tonga, or Friendly, Islands, the Ellice and Gilbert groups, and the British Solomon Islands). In the foregoing colonies and protectorates, except Bahamas, Barbados, Bermuda, British Honduras, and the Leeward Islands, the crown has the power of legislating by order in council.

Not included in the classification above, but of proper place in an enumeration of the components of the British Empire, are the following: Northern Rhodesia and Southern Rhodesia (under the control of the British South Africa Company); the protected state of Brunei; the protected states of Johore, Kedah, Perlis, Kelantan, Trengganu, and the Federated Malay States; also the following possessions which are not administered under the Secretary of State for the Colonies: North Borneo, a protected state under the jurisdiction of the British North Borneo Company, Sarawak (protectorate), Zanzibar (protectorate), Aden (administratively a part of the Bombay Presidency), with Perim, Socotra, and other islands, Ascension, Tristan da Cunha, and other small islands. There must also be mentioned the Isle of Man (with a governor and a representative assembly) and the Channel Islands (with lieutenant governors and elective legislative bodies). There remains what in many ways is the most important of all the British possessions, an empire in itself, India.

It consists of "British territory" and "native states." The British territory is administered by the governor-general of India in council, appointed by the crown and subject to the Secretary of State for India at London, the native states are governed by their own princes, each under the control of a British resident (for details of government, executive and legislative, see INDIA, BRITISH). The independent states of Nepal and Bhutan are in some degree under British control.

Egypt, though under Turkish suzerainty, is virtually controlled by the British government, and the development of the country in recent years is due largely to the dominating influence of the British agent and consul general, minister plenipotentiary. The reclamation and development of the Sudanese provinces (the Anglo-Egyptian Sudan) have gone forward since 1890 under the condominium of the British and Egyptian governments.

In the case of colonies the officer appointed by the crown to administer the government is styled in accordance with the status of the colony, governor-general and commander in chief, governor and commander in chief, or captain general and governor in chief. In the case of protectorates (under the Secretary of State for the Colonies) the administrative officer appointed by the crown is styled either governor and commander in chief, high commissioner, commissioner and commander in chief, or commissioner.

The term "British Empire" must not be regarded as signifying so definite an entity as does, for instance, the term "Russian Empire." This is due in large measure to the wide dispersion of the British territories, to their heterogeneous elements of population, and to the diverse forms of government or degrees of autonomy possessed by them. From about 1880, however, the idea of British imperialism and solidarity has shown a notable development. This came into especial prominence at the time of the Boer War of 1899-1902 and has been emphasized by the proceedings of subsequent Imperial conferences and by the manifest desire of the great self-governing dominions to take an active part in Imperial defense.

The area and population of the British Empire are stated as follows, the figures for population being those of the census or estimates of 1911:

	Sq miles	Population
England	50,374	34,045,290
Wales	7,490	2,025,202
Scotland	30,405	4,700,904
Ireland	32,360	4,500,219
Total, United Kingdom....	121,105	45,251,615
Isle of Man	227	52,094
Channel Islands	75	95,900
British India	1,003,074	244,207,542
Native States	709,118	70,864,995
Total, India	1,802,192	315,132,537
Aden, incl. Perim (included above under British India)	80	46,165
Socotra	1,382	(a) 12,000
Straits Settlements	1,630	714,000
Ceylon (b)	25,332	4,106,350
Mauritius	720	368,791
Dependencies of Mauritius	89	6,600
Seychelles	156	22,601
Hongkong (c)	390	306,145
New Territories (d)	390	90,594
Weihaiwei	285	147,193

The table above includes the colonies and the African protectorates (except Zanzibar). The remaining protectorates include the following

	Sq miles	Population
Commonwealth of Australia		
New South Wales	309,460	1,646,734
Victoria	87,584	1,315,551
Queensland	670,500	605,313
South Australia	380,070	408,558
Western Australia	975,920	282,114
Tasmania	26,215	151,211
Northern Territory	523,520	3,310
Federal Capital Territory	912	1,714
Total, Commonwealth (e)	2,974,581	4,455,005
Territory of Papua	90,340	400,000
Dominion of New Zealand	104,356	1,008,468

British Solomon Islands Protectorate	14,800	150,500
Gilbert and Ellice Islands protectorates	180	31,121
Tonga, or Friendly, Islands Protectorate	390	21,695
Zanzibar Protectorate	1,020	198,914
Total	145,912	3,075,451

Various small Pacific islands are attached to New Zealand or the Solomon, Gilbert, and Ellice, or Tonga protectorates. Pitcairn Island (area 2 square miles, pop, 144) is regarded as a colony. In addition there are various small islands which are British territory or are under British protection, but which are not included in any colony or protectorate. At the Bahrein Islands (pop about 90,000), in the Persian Gulf, is a British political agent. From the foregoing figures it appears that the total area of the United Kingdom and the territories under its administration or control (not including Egypt or the Anglo-Egyptian Sudan) is about 11,520,000 square miles, with a population (1911) of over 422,076,000. The actual population figure is even somewhat larger than this, for the census returns of the United Kingdom do not include the army, the navy, or merchant seamen abroad, also some of the colonial returns do not include the military or persons on board ships in harbors.

BRITISH GUIANA. See GUIANA.

BRITISH GUM. A name given commercially to dextrin (q.v.).

BRITISH HONDURAS. A British crown colony in Central America (Map Central America, C 2). It is bounded by Guatemala on the south and west, Mexico on the northwest, and the Caribbean Sea on the east, and covers an area, including numerous cays, of 8598 square miles. The coast is, as a rule, low and swampy, and a large part of the interior is covered with forests yielding large quantities of mahogany and logwood. The climate is hot, moist, and generally unhealthy for Europeans. Over 50,000 acres are under cultivation and yield fruits, rubber, coffee, etc. Estimated area-

(a) Estimated population 1910. (b) Excluding the military and persons on ships in harbors. (c) Population excluding the military. (d) The New Territories and Weihaiwei were leased to the British government in 1898. In 1904 a part of the New Territories (New Kowloon) was placed under the jurisdiction of the Hongkong Sanitary Board, and since that date the area (13 square miles) and the population (13,693 in 1911) have been included in the figures for Hongkong. (e) Exclusive of full-blooded aborigines, estimated at 100,000. (f) Partly estimated. (g) Including the area of the lakes and river Nile within the protectorate. (h) Including the protectorate districts. (i) Including part of the Grenadines.

age of worked mahogany and logwood forest, 2,615,000, yielding 13,020,580 superficial feet of mahogany and 3231 tons of logwood in 1911. Of cedar, 1,543,744 superficial feet were exported in 1911. In order to open up the country the government in 1904 sold to B. Clupley, an American, at one cent per tree, all pine trees on crown lands. Total imports in 1911, \$2,886,077 (\$1,227,903 in 1902); total exports, \$2,685,849 (\$1,302,210 in 1902). The fruit export was 2,653,445 plantains, 5,198,999 coconuts, 450,365 bunches of bananas. Exports of sapodilla gum, 3,219,990 pounds; rubber, 24,192 pounds; sponges, 9822 pounds; tortoise shell, 3367 pounds. About 25 per cent of the commerce is with Great Britain. The revenue, derived chiefly from taxes, duties, and sale and letting of crown lands, was \$1,201,908 in 1911-12; the expenditure, \$532,123. The public debt amounted at the end of 1911 to \$946,415. The colony is administered by a governor, and has an executive and a legislative council. United States gold currency was adopted as a legal tender in 1894. Pop., census of 1911, 40,458; about 600 are whites, the rest being negroes, mulattoes, and Indians; in 1901, 37,479. The capital, Belize, is a busy port, with an extensive shipping and a population in 1911 of 10,478. The colony was first settled at the beginning of the eighteenth century by the Scotch adventurer Wallis, from whom it is supposed to have received its original name of Belize (Balize). Spain made numerous attempts to expel the early British settlers from the colony, and it was not until 1798 that a treaty was concluded which permitted peaceful development of the country; and not till 1896 was Great Britain entirely confirmed in its possession.

BRITISH INDIA. A term used to designate the districts of India under direct British administration, in contradistinction to the native states under British protection. The area of British territory is stated at 1,093,074 square miles; native states, 709,118 square miles; total India in British possession or under British control, 1,802,192 square miles. Pop. of British territory in 1911, 244,267,542; native states, 70,864,995. See INDIA.

BRITISH MUSEUM. An important national institution in London. By the will of Sir Hans Sloane (q.v.), his great natural history and art collections, with a large number of books and manuscripts, were in 1753 offered to the government for £20,000, the first cost having been over £50,000. The necessary funds were raised by a lottery, and the collection, together with the Harleian and Cottonian libraries (the latter of which, presented to the nation in 1700, was the real beginning of the museum), bought for the purpose. The institution was established in Montague House, which was opened in 1769 under the name it now bears. The acquisition of new collections made enlargement necessary; and finally, in 1823, the eastern wing of the present building was erected, to receive the library of George III. The completion of the structure was delayed, however, until 1847. It is a hollow square, Ionic in architecture, with an imposing façade 370 feet long on Great Russell Street, flanked by the residences of the chief officers. The principal subsequent addition was the splendid reading room erected (1854-57) within the quadrangle, at a cost of £150,000. It is circular in form, with a dome

106 feet in height and 140 in diameter. The library of the museum contains over 3 miles of bookcases, 8 feet high, which is equivalent to space for 1,000,000 octavo volumes. The reading room proper in the dome contains 60,000 more. It has accommodation for 200 readers, and in details of arrangement, ventilation, etc., is admirably adapted to its purpose, thanks very largely to the unwearied care of Sir Antonio (then Mr.) Panizzi (q.v.), the principal librarian, during its construction. When the natural-history departments claimed more space, a new building was erected for their exclusive use in Cromwell Road, near the South Kensington Museum, at a cost of nearly £400,000. To this, which has been in use since 1881, the zoological, mineralogical, geological, and botanical departments were transferred, all very rich in specimens and constantly expanding. In 1873 and 1888 the main building was also considerably enlarged for the benefit of the departments of Greek sculpture and of prints; and in 1895 several acres of ground adjoining were secured for future extension, which has now (1913) been completed.

Only a brief account can be given of the wealth of collections contained in the museum. They were originally arranged in three departments—printed books, manuscripts, and objects of natural history. There are now eight departments in the museum proper. Access to the library is granted by the issuing of a reader's ticket, on a written application accompanied by the recommendation of a London householder. The total number of persons visiting the general collections in 1911 was 723,571. Those using the library during the same year numbered 223,404. The total number of volumes supplied during the year closely approximated 1,500,000 volumes, exclusive of the 20,000 volumes on the open shelves.

Printed Books.—This is the largest department and, from Sir Hans Sloane's original collection of 50,000 volumes, has grown to enormous proportions, by purchase, bequests, and donations. Under the Copyright Act of 1842 it receives a copy of every book published in England. The annual increase from all sources is nearly 50,000 volumes, and the total number of printed books is now between 3,500,000, and 4,000,000, which is hardly exceeded by the Bibliothèque Nationale in Paris. The old manuscript catalogue, which used to extend to some 3000 volumes, has at last been superseded by a printed one, begun in 1881 under the supervision of the learned librarian, Dr. Garnett, and requiring about 600 volumes. The most extensive and valuable additions have been the royal collections given by the last three Georges, David Garrick's collection of plays (1779), the natural-history library of Sir Joseph Banks (1820), and the Grenville collection (1847). Over 50,000 printed and 20,000 manuscript maps form a special subdepartment. In 1912 Alfred H. Euth bequeathed 13 illuminated manuscripts and 37 rare books to the museum's collection, which constitutes the most valuable gift made to it since the Grenville Library.

Manuscript Department.—This now contains upward of 55,000 volumes, besides charters, seals, and Egyptian, Greek, and Roman papyri. It includes the Cottonian manuscripts (see COTTON, SIR ROBERT BRETOM), rich in documents relating to English history; the Harleian collec-

tions (see HARLEY, ROBERT), specially rich in illuminated and classical manuscripts, those from the royal library given by George II in 1757, and containing, among other very valuable things, the Codex Alexandrinus (q.v. under BIBLE), the Psalterion of James I in his own handwriting, and many priceless literary autographs. The most important recent additions to this department are the Stowe manuscripts, purchased from Lord Ashburnham, and 430 volumes of the Duke of Newcastle's papers.

There is a separate department of Oriental printed books and manuscripts, established in 1892, and the former antiquities department, dating from 1807, was in 1861 divided into the three which follow.

Greek and Roman Antiquities—Sir Hans Sloane's small collection was the nucleus of this department, which for a number of years made slow progress. In 1772, by the purchase of Sir W. Hamilton's collections, a number of important vases were secured, and at the end of the same century the Dilettanti Society (q.v.) gave the results of their expedition to Ionia. In 1805 the collection of Greek Roman sculpture formed by Charles Townley was purchased for £20,000, to be followed in 1814 by the Townley collection of bronzes, gems, and coins. In the same year the frieze of the temple of Apollo at Bassæ (see PHIGALIAN MARBLES) was purchased. It was, however, in 1816 that the most valuable accession reached the museum, in the shape of the Elgin Marbles (q.v.), purchased for £35,000, and including the statues and reliefs from the Parthenon. Since then the display of sculpture has been increased by the Lycian monuments brought back by Sir Charles Fellows (1842), and by the results of the excavations at Halicarnassus, Cyrene, Ephesus, and Priene, as well as by the purchase of collections and single monuments. To the vases and small objects have been added the Burgon and other collections, including a valuable series of vases from Camiros and Naukratis. The collection of gold, silver, and gems was greatly enriched by the addition of the Castellani collections in 1872-73. This department was enriched by three most important accessions during 1911.

Coins and Metals—This department, whose beginning came from the Cotton and Sloane collections, has grown to be a large and interesting department, arranged as Greek, Roman, Mediæval and Modern English, and Oriental. In 1872 £10,000 were spent in purchasing the finest Greek and Roman specimens of the Wigan collection. In 1911 a collection of 2600 coins (173 in gold) was added to this department through the generosity of Henry van den Bergh.

Egyptian and Assyrian Antiquities (until 1881 called Oriental Antiquities)—This collection began with the antiquities which fell into British hands at the capture of Alexandria in 1801, but its most valuable acquisitions date from the middle of the century and are due to Layard, Rawlinson, George Smith, and other famous explorers. It is now a singularly complete and varied collection of Egyptian, Babylonian, Assyrian, Phœnician, and Semitic antiquities. Considerable accessions were made in 1911 of scarabs of the Hyksos period, Coptic and Illyrian antiquities, etc.

British and Mediæval Antiquities and Ethnographic Collections—This was made a separate department in 1866, and contains all ob-

jects of this nature found in the British Isles, and others which throw light on life in the Middle Ages. The Christy and Slade collections have added much to its value. A large number of accessions, due to the generosity of private benefactors, were made to this department of the museum in 1911.

Prints and Drawings—This magnificent collection, one of the most complete and valuable of its kind, is arranged in schools, according to the different styles of national art, now including the Japanese, and comprises original drawings of the old masters, etchings, and engravings. The most recent addition of prominence is the famous collection of John Malcolm. In 1911 the accessions of this department included a considerable number of rare German woodcuts and engravings, a collection of studies of birds and animals, and a large number of drawings, etchings, and engraved portraits—all the gifts of private benefactors.

The expenses of the maintenance and enlargement of the museum are paid out of the national treasury. For 1912-13 the administrative expenses of the museum are estimated to exceed £205,000. The whole system of arrangement facilitates the use of its collections by students, excellent catalogues and handbooks exist, and, as far as possible, all objects are clearly labeled. Its educational value is very great, and that it is appreciated is shown by the fact that, in 1911, 659,786 persons visited the museum on week days alone, while those who used the reading room averaged 745 daily. One of the new departures made recently is the engagement of official guides, who conduct parties through the museum free of charge and explain its most interesting features.

BRITISH NAVY See GREAT BRITAIN

BRITISH SOMALILAND See SOMALILAND, PROTECTORATE

BRITISH WEST INDIES A political division of the West Indies, comprising Jamaica and almost all the smaller islands of the Antilles, with the exception of a few small islands belonging to France, Denmark, and the Netherlands. They are divided into the following groups.

GROUPS	Area Sq. miles	Population
Bahamas	4,404	55,944 (1911)
Barbados	166	171,592 (1911)
Jamaica with Turks, Caicos, and Cayman Islands and Morant and Pedro Cays	4,424	831,333 (1911)
Leeward Islands	715	157,139 (1911)
Trinidad with Tobago	1,368	339,093 (1911)
Windward Islands	*527	*164,150 (1911)
Total	12,105	1,680,651

* Including Grenada, St. Vincent, St. Lucia, and Curacao.

These groups are subdivided into administrative units with different forms of government. The chief means of subsistence with all of them is agriculture, sugar and fruit constituting the staple products. The population consists mostly of negroes and mulattoes. For more details, see articles on the separate islands and groups. Consult Jay, *A Glimpse of the Tropics* (London, 1900); Fiske, *History of the West Indies* (New York, 1899); Root, *The British West Indies and the Sugar Industry* (London, 1899); Report of

the West India Royal Commission (ib., 1897); Rodway, *The West Indies and the Spanish Main* (ib., 1896); Macmillan, *The West Indies* (ib., 1909); Oliver, *Caribbean* (ib., 1910-12).

BRITO CAPELLO, bré'tôô kâ-pêl'ôô, HERMENEGILDO AUGUSTO DE (1839-). A Portuguese naval officer and African traveler, born in Lisbon. He became a captain in the royal navy in 1880. In 1877 he was sent by the government with Major Serpa Pinto and Roberto Ivens to explore the Portuguese colony of Angola. In order to make their expedition of greater scientific value, they decided to explore separate parts of Portuguese Africa; so while Serpa Pinto crossed Africa from Loanda to Durban, Ivens and Brito Capello (the latter of whom was already well known as a meteorologist) visited West and Central Africa, and explored the basin of the Kuango from the headwaters of that river to the Yaka district. They returned to Lisbon in 1880. With Ivens he was again dispatched by the government in March, 1884, to traverse the southern part of the continent from Portuguese West Africa (Angola) to Portuguese East Africa. He explored Amboella and the watershed between the Kongo-Lualaba and Zambezi rivers and directed his course along the Zambezi from Zumbo to Quilimane on the eastern coast, where he arrived in May, 1885. On both these journeys these two explorers made more than 60 astronomical determinations, and many magnetic and meteorological observations. They made also ethnographical, zoological, botanical, and mineralogical collections, and were rewarded in 1886 by the Paris Geographical Society which awarded them its grand gold medal for that year. The previous year they had both been honored in Madrid by splendid receptions and by honorary corresponding membership in the Madrid Geographical Society; and Brito Capello had been granted the Military-Naval Grand Cross. In collaboration with Ivens he wrote *De Benguella as terras de Jacca* (1881) and *De Angola á Contra-Costa* (1886). Each of these works is in 2 volumes and illustrated. In 1887 Brito Capello was appointed Portuguese Commissioner to discuss the boundaries of the Sultanate of Zanzibar and the colony of Mozambique. Later he was appointed Governor of the province of Loanda.

BRITO-FREIRE, bré'tôô frâ'râ, FRANCISCO DE (c.1620-92). A Portuguese soldier, naval officer, and historian. He became a captain of cavalry in the land forces, and in 1655 and 1656 commanded the fleet in the war which culminated in the expulsion of the Dutch from Brazil. He is best known for his *Nova Lusitania, Historia da Guerra Brasileira* (Lisbon, 1675), a rare and important work. He is also author of *Relação da viagem que fez ao Estado do Brasil a armada da companhia [do Commercio], anno 1655* (Lisbon, 1657).

BRITOMAR-TIS (Gk. *Borēmaptris*, translated by later Latin authors by *virgo dulcis*, sweet maiden, from Cretan *brity*, rich in blessing + *maris*, maiden). A Cretan female deity. Greek myth holds her to have been originally a nymph, daughter of Zeus and Carme, who drowned herself to avoid the embraces of Minos and was apotheosized by Artemis. According to another story she was not drowned, but fell into some fishermen's nets and was afterward deified as Dictynna (cf. Greek *δίκτυον*, *diktynon*, a net). She came to be regarded as the virgin patron of the chase, as Artemis was, and as

such is used by Spenser in the *Faerie Queene* to symbolize, in the form of a chaste huntress, Elizabeth, the Queen brave and unwedded.

BRITSKA (Russ. *britshka*, Pol. *bryczka*, dim. of *bryka*, a freight wagon). A long four-wheeled pleasure carriage, in use in Russia and Poland, so constructed as to give space for reclining at night, when used on a journey. The Polish *britska*, employed also in Russia, has a pole, a body of wickerwork, and a leather top. This type of carriage was introduced into Great Britain about 1818 and for a few years had an extraordinary vogue.

BRIT'TANY, Fr. **BRETAGNE**, bré-tá'ny' (from the *Bretons*, its inhabitants). Anciently **ARMORICA**. A peninsula of triangular form in the northwest of France (anciently a Roman province, subsequently a duchy, afterward again a province) nearly corresponding to the departments of Finistère, Côtes-du-Nord, Morbihan, Loire-Inférieure, and Ille-et-Vilaine. It has the English Channel on the north, the Bay of Biscay on the south, and the Atlantic Ocean on the west. The boundaries on the land side are the old provinces of Normandy, Maine, Anjou, and Poitou. The ancient duchy was diagonally divided from northwest to southeast into Haute and Basse Bretagne (Upper and Lower Brittany), the capitals of which were respectively Rennes and Vannes. The coast generally rises in rugged and lofty cliffs, but is indented with numerous bays which afford ample commercial advantages. Saint-Malo, Saint-Brieuc, Brest, Quimper, Lorient, and Nantes are important seaports. From the Montagnes d'Arrée and the Montagnes Noires, masses of granite in the northwest, the modern designation of Côtes-du-Nord—Northwest Hills—is derived. While not exceeding a height of 1150 feet, they give to the peninsula a bold and imposing appearance. The centre of the country is formed chiefly of clay slate. The scenery is varied and beautiful, and although the winter months are marked by fogs and violent wind storms, the climate generally is dry, bracing, healthful, and favored with much sunshine.

Large tracts of land lie uncultivated; but in the well-watered valleys, along the numerous rivers, and especially in the northern parts, modern methods yield abundant crops of all kinds, railway and steamboat transportation facilities giving a great impetus to agriculture. In the west and southwest agriculture is still in a primitive state, and there the tenacity with which the Breton clings to the customs and beliefs of his forefathers is especially apparent by his retention of the Celtic language, rich in folklore and an individual literature, and by his quaint, picturesque, and multi-colored sixteenth-century costume, always in evidence on Sundays and at festivals and fairs. The legends and traditions of the marvelous, which still influence the simple, superstitious native nature, are enhanced by the stupendous megalithic monuments of the Paleolithic Age which abound on the plains of Carnac, at Locmariaquer, Dol, and other localities throughout the region—relics of the pagan religion which existed as late as the seventeenth century, ritual traces of which secretly survive in remote parts. The Bretons are an Alpine or Celtic people, classed by Deniker, *Races of Europe* (1900), as dark, very brachycephalic, and short, and called by him the Western or Cévenole race (cranial index, 82.7; height, 1.63 meters). They have brown or black

hair, light or dark brown eyes, rounded faces and thickset figures. Traversed by railroads and fine highways, Brittany is a great resort for tourists—cyclists and automobilists especially being attracted by the combination of beautiful scenery and the archaic atmosphere of ancient monuments, castles, cathedrals, churches, and picturesque, if not particularly clean, villages.

History In ancient times Brittany, under the name of Armorica (q.v.) or Aremorica, was the seat of the confederated Armorican tribes who were of Celtic and Kymric origin. Traces of them remain in the old Kymric dialect of the three most westerly departments, and in the numerous so-called Druidical monuments already mentioned. The Armorici passed finally under Roman control in 61 B.C. Under the Romans the country was made the *Provincia Lugdunensis Tertia* and for two centuries was prosperous under the "Roman peace." But in the disorders of the third century A.D. it suffered severely and was reduced almost to a wilderness. It was repopled by numerous immigrations from Great Britain caused by the Anglo-Saxon invasions of the fifth and the sixth centuries, and then its name was changed from Armorica to Brittany—*Britannia Minor*. Monasteries were built, and settlements arose about them. Soon the Franks came into collision with the Bretons. From the time of Clovis (q.v.) to the death of Charlemagne there were frequent wars in which the Bretons were usually defeated, but never subdued. They paid tribute only when compelled by an armed force. Louis the Pious placed a native chief, Nomenoe, over the country in 818, and under his rule it prospered. After the battle of Fontenay, 841, Nomenoe took advantage of the weakness of the Carolingian monarchs to establish his independence, which was recognized in 846. From this time the rulers claimed the title of "Duke by the Grace of God." Brittany suffered severely from the invasion of the Northmen, but won a temporary respite by a brilliant victory in 891, when of 15,000 Northmen only 400 escaped. After 907, however, the Northmen renewed their attacks and reduced the country to the same desperate condition in which it had been in the fourth century, "Brittany destroyed," in the words of contemporary writers. Alain of the Twisted Beard (who died in 952) drove out many of the Northmen, but the country remained a prey to civil strife. In 992 Geoffrey, Count of Rennes, an ally of the Normans, took the title of Duke of Brittany, though the French King refused to acknowledge the legitimacy of the title till 1213. After the tenth century Brittany was closely associated with Normandy, and many Britons took part in the conquest of England. Under Henry II of England the Duke had to flee to England, and Henry took advantage of the opportunity to make his son Geoffrey Duke of Brittany in 1169. Geoffrey soon became the ally of the King of France against his own father. His posthumous son, Arthur, was the unhappy prince whom Richard the Lion-Hearted declared his heir, and King John was suspected of murdering, in 1203. After that Brittany became a vassal state of France, and in spite of frequent revolts remained so until about 1338. Then, when war broke out between England and France, the French King was glad to secure the Duke's aid "as an ally, not as a subject." During the Hundred Years' War Brittany was the ally alternately of each party and suffered exceedingly.

The question whether Brittany was a vassal state of France remained undecided and caused many wars. In 1491 the Duchess Anne, heiress of Brittany, married perforce Charles VIII. of France and the duchy was united to France. In 1499, however, when Anne married Louis XII., the successor of Charles VIII., the independence of Brittany was again fully recognized. After long discussion and many treaties the duchy was declared incorporated with France in 1532 by Francis I. Brittany retained a local parliament until the outbreak of the Revolution. During the Revolution Brittany, which was loyal to the Bourbons, was the arena of sanguinary conflicts, and especially of the uprising of the Chouans (q.v.), who reappeared as recently as 1832. Consult Borderie, *Histoire de Bretagne* (1896), Menpes, *Brittany* (New York, 1905), Raison du Cleuzon, *La Bretagne de l'origine à la réunion* (Paris, 1909).

BRITTLE, Mrs. The unfaithful wife of Barnaby and the title character in Betterton's *Amorous Widow*. The part was a favorite with Mrs. Bracegirdle, who, in 1706-07, at the Haymarket, chose it to show her histrionic powers, as contrasted with those of Mrs. Oldfield. For the cause and result of the latter remarkable contest, consult *Life of Mrs. Oldfield*, anonymous (London, 1730), Genest, *Account of the English Stage*, vol. II (Bath, 1832).

BRITTLE STARS (so called from being brittle or fragile). A class of starfish-like echinoderms, technically known as *Ophiuroidea*, excluding the basket fish (q.v.). The brittle stars are a widely distributed group of animals, like all the echinoderms, exclusively marine, found in all seas, but most abundant in the tropics and especially in the West Indian region. They are common at all depths, but are especially abundant in comparatively shallow water. None of them reach a very large size, few having the body or disk more than an inch in diameter, and the arms or rays are rarely 10 inches in length. In color there is the most extraordinary variety. While some are black, brown, dull olive, or even pure white, others are of the most gorgeous shades of green, blue, red, and yellow, or exhibit the most beautiful combinations of hues. In some the disk is smooth and the arms terete, with very short, flat, and appressed arm spines, in others the whole disk is covered with spines, sometimes short and opaque, but often long, slender, and glassy, and the flattened arms bear very long and beautifully transparent arm spines. In fact, the variety in the shape and covering of the disk and arms is quite as great as that in color. The arms, though flexible from side to side, are very slightly flexible up and down, and are therefore very easily broken. It is from this circumstance that the name "brittle star" has arisen. They are usually rather slow-moving animals, with little power of escaping from their enemies, and with no means of defense save such as the spines afford. Accordingly they live under rocks or buried in mud or sand, where there is little danger of their being seen. A few species, however, show considerable agility in escaping from an enemy and run about rapidly from rock to rock as they are pursued. They are practically all vegetable feeders or scavengers, though possibly some are carnivorous. About 600 species of brittle stars are known, of which only a few are found along the shores of the United States. About half a dozen forms

occur in shallow water along shore, north of Cape Hatteras, but south of that point they become very abundant. The Pacific coast forms are at present very slightly known.

BRITTON. The putative author of the earliest summary of the laws of England in the French language, all earlier treatises having been written in Latin. (See BRACON.) It was prepared in the last decade of the thirteenth century (probably 1292-94) and purports to have been written by the command of Edward I and speaks in his name. The author of the treatise is unknown, but he was probably a clerk or lawyer attached to the King's court, who sheltered himself behind the greater writer, whom we know as Bracton, but whose name was variously spelled Bratton, Bretton, or Britton, and whose work was largely drawn upon by the anonymous author of the present compilation. The latter is not a mere transcript of the greater work, however, but an original treatise of considerable value. An incomplete translation by Robert Kelham was published about the middle of the eighteenth century, and in 1865 appeared Francis M. Nichols's admirable edition, with an excellent translation, commentary, and learned introduction, published in London. Nichols's translation has been republished in the United States (Washington, 1902), with an introduction by Judge Simon E. Baldwin.

BRITTON, COLONEL. One of the principal characters in Mrs. Centlivre's comedy *The Wonder, a Woman Keeps a Secret*.

BRITTON, ELIZABETH GERTRUDE (1858-). An American bryologist, born in New York, a daughter of James Knight. Her early years were spent in Cuba. She graduated from the New York Normal College, where later she taught in the training department (1875-82) and was assistant botanist (1882-85). After her marriage to Nathaniel Lord Britton (q.v.) in 1885 she became editor of the *Bulletin of the Torrey Botanical Club* (1885-88). She continued the study of mosses, begun in 1880, and devoted much of her time to improving the collections of Columbia University and the New York Botanical Garden. She became known as a frequent contributor to botanical journals of papers on mosses and ferns.

BRITTON, HENRY DE. See BRACON.

BRITTON, JOHN (1771-1857). An English antiquarian, born in Wiltshire. His first literary work was a collection of popular songs. Then with Edward Wedlake Brayley (1773-1854), an enameleur, he compiled *The Beauties of Wiltshire* (vols. i, ii, 1801; vol. iii, 1825), the beginning of a series called *The Beauties of England and Wales*. He wrote *The Architectural Antiquities of England* (5 vols., 1805-26) and *The Cathedral Antiquities of England* (14 vols., 1814-32). He was a pioneer in the work of preserving "ancient monuments." He attempted (1848) to prove that Isaac Barré wrote the letters of "Junius." Consult his *Autobiography* (2 vols., London, 1849-50).

BRITTON, NATHANIEL LORD (1859-). An American botanist, born at New Dorp, Staten Island. He was educated at Columbia University, where he was assistant in geology (1879-80), instructor in geology, botany, and zoology (1880-90), and adjunct professor (1891-96). Having retired as professor emeritus in 1896, he became director in chief of the New York Botanical Garden. For five years he was a member of the New Jersey Geological Survey,

and in 1882 he served as field assistant on the United States Geological Survey. Besides editing the *Bulletin of the Torrey Botanical Club* (1888-98), he wrote *Illustrated Flora of Northern United States and Canada*, with Addison Brown (3 vols., 1896-98; 2d ed. rev. and enlarged, 1913); *Manual of the Flora of the Northern States and Canada* (1901; 2d ed., 1907); *North American Trees* (1908); *Studies in Cactaceae* (1913).

BRIVES-LA-GAILLARDE, brev'là-gà'yàrd' (Fr. joyful Brive, anciently, Lat. *Briva Curetia*, town on the Corrèze, from Celt. *bragh*, *brig*, heap, pile, elevation). A manufacturing town in the department of Corrèze, France, on a river of that name, situated about 18 miles southwest of Tulle (Map: France, S. F. 3). It is a beautiful city, with many interesting old houses and several churches (one of which, St. Martin, dates from the eleventh century), a college and a library. Near by are rock caves of prehistoric times. On account of its position it is a market of importance and does an active trade in vegetables, fruit, grain, wool, wine, live stock, and oil. There are manufactories of copper and tinware, paper, hats, wooden shoes, wax candles, and truffle pâtés, dye works, and quarries of slate and millstone. Pop., 1901, 17,049; 1911, 21,486. The Romano-Gallic name of the place was *Briva Curetia*. It is the birthplace of Cardinal Dubois.

BRIXEN (It. *Bressano*; anciently Lat. *Brivantes*, Gk. Βριζάντα, *Brivántai*, probably "mountaineers," from Celt. *brig*, elevation, hill). A town of the Austrian crownland of Tyrol, situated about 1835 feet above sea level, and about 60 miles east-southeast of Innsbruck, on the right bank of the Eisak at its confluence with the Rienz (Map: Austria, B. 3). It is an episcopal see and has a handsome episcopal palace, a fine cathedral, dating from the fifteenth century and containing the tomb of the Minnesinger Oswald von Wolkenstein, and several monasteries. The chief industry is the production of wine and the raising of fruit and grain. About 5 miles north-northwest of the town, is the fortress of Franzensfeste, commanding the Brenner Pass and the entrance to the Pustertal. Pop. of the district in 1910, 18,573. Brixen is mentioned in 901, and since 992 has been the capital of an episcopal see established in the fourth century.

BRIXHAM (AS. *brycg*, *brieg*, Ger. *Brücke*, bridge + *hām*, Ger. *Heim*, home, i.e., town of the bridge). A market town and seaport of Devonshire, England, beautifully situated on the south side of Torbay, 33 miles south of Exeter (Map: England, C 6). The town occupies the sides of two hills and is divided into two parts, called Upper and Lower Brixham. The prosperity of Brixham depends chiefly on its fisheries, it being the headquarters of the great Devonshire fishery of Torbay, in which many vessels are employed. Other industries include shipbuilding and the making of paint, ropes, and sails. The town is a much-frequented seaside resort. A cave discovered on Windmill Hill in 1853 is famous for the remains of prehistoric animals and man found there. It was at Brixham that the Prince of Orange (afterwards William III) landed, Nov. 4, 1688. Pop., 1871, 4941; 1891, 7078; 1901, 8000; 1911, 7054.

BRIXIA. See BRESCIA.

BRIZA. See QUAKING GRASS.

BRIZEUX, bré'zè', JULIEN AUGUSTE PÉLAGE

(1803-58) A French poet. He was born in Lorient, Bretagne, and in 1831 published his very successful idyllic poem, *Marse*. Most of his work derives its *motif* from the Bretagne country and rings freshly and sincerely. He wrote further *Les Ternaires*, afterward called *La fleur d'or* (1841), *Les Bretons* (1845), and *Ilistoves poétiques* (1855), the last two crowned by the Academy. His *Œuvres complètes* were published in 1870-84 (4 vols). C. Leconte published a life of Brizeux in 1898 (Paris).

BRIZURE, bié-zu', Brizé, or BRISÉ (Fr. *brisé*, from *briser*, to break). Terms used to indicate that a charge is bruised or broken, also the abatements or bearings by which the arms of a family are broken or diminished. See **IMPALDRY**.

BROACH, bröch, or BAROACH (*Barygaza* in the *Periplus* of the first century A.D., from Skt *Bharygachcha*, the town of Bhiga in the Seer, from *Kuacha*, river bank). A town of British India, in the presidency of Bombay, 203 miles north of Bombay (Map India, B 4). It is situated on an elevated mound, supposed to be artificial, on the north bank of the Neibudda, which is here 2 miles wide even at ebb tide, but shallow. The navigable channel is winding and difficult, even at high water—a feature mentioned as early as the first century A.D. It abounds in fine fish. A stone wall, about 40 feet high, fronts the river bank and protects the town from inundation. The streets are narrow, with tall houses. Situated in the midst of a fertile district, for 800 years it was a flourishing town, with a large population, but in consequence of political troubles, and the rise of Surat in the sixteenth century, it began to decay. Its trade consists chiefly of agricultural products and cotton. Broach was long famous for its manufactures of cloth, but that of the finer kinds declined, owing to the importation of English goods. Many of the weavers of Broach are Parsis, of whom some are of the more opulent classes—as shipowners and ship brokers. Broach has a remarkable Brahmanical hospital for sick animals, into which horses, dogs, cats, monkeys, peacocks, and even insects are received. It is ostensibly conducted by a number of Brahmans, who derive a good income from lands devoted to it and from voluntary contributions. Broach belonged to the Kingdom of Guzerat, on the overthrow of which by the Emperor Akbar was assigned to a petty Nawab. Falling under the dominion of the Peishwa of the Mahadattas, it was taken by the British in 1772, ceded to Scindia in 1783, in acknowledgment of the kind treatment of some British prisoners, and again stormed by a British force in 1803, since which date it has remained in the possession of the British. Pop., 1901, 42,806, 1911, 43,403.

BROAD ARROW. A conventionalized arrowhead which forms the government mark on British government stores.

BROAD/BENT, SIR WILLIAM HENRY (1835-1907). An English physician and author. He was educated at Owens College, the Royal School of Medicine in Manchester, and in Paris, and was appointed physician to the Western General Dispensary. Subsequently he was physician successively to the London Fever Hospital and St. Mary's Hospital and in 1881 became president of the Medical Society of London. In 1888 and 1889, and again in 1895 and 1896, he was censor of the Royal College of Physicians, in

1898-1901 was physician extraordinary to Queen Victoria, and in 1901 became physician in ordinary to King Edward VII. He published *The Pulse* (1890) and *The Heart* (1897). A volume of selections from his writings was edited and published by Walter Broadbent in 1908, and his *Life*, by his daughter, in 1909.

BROADBILL. A bird having a notable breadth of beak. 1. A scaup duck, or "bluebill" (See **SCAUP**). 2. The shoveler duck. (See **SHOVELER** and **PLATE OF DUCKS**). 3. The spoon-bill (q.v.). 4. A broadmouth (q.v.). 5. A bird. See **PLATE OF LYRE BIRD**, etc.

BROAD-BOTTOM ADMINISTRATION. A name derisively given to the English ministry formed by Henry Pelham in 1744, because it professed to include in a grand coalition all parties of weight and influence in the state, and comprised no less than nine ducks. The same phrase was applied also to Cartier's ministry (1742-44) by Horace Walpole.

BROADCASTING. A method of sowing which distributes the seed with some uniformity. When done by hand, the seed is carried in a bag at the left side and is scattered with the right hand as the sower walks. It is afterward covered with a harrow or by dragging brush over it. Machines for sowing grain or other seed are called broadcast seeders. The method of sowing by the drill is generally preferred. Broadcasting is largely limited to the sowing of spring grains and grasses.

BROAD CHURCH PARTY. A name loosely applied, from about the year 1850 onward, to a group of liberal leaders in the Church of England, of whom Thomas Arnold, Frederick Denison Maurice, Charles Kingsley, Frederick William Robertson, and Arthur Penrhyn Stanley were the most important. In their breadth of view they resemble the Latitudinarians of the seventeenth century—Cudworth, Whitchote, and More. The designation "Broad" churchmen is not wholly satisfactory and was disavowed by the leaders of the movement themselves. Its historic justification, however, lies in the fact that it describes the tendency towards doctrinal comprehensiveness, long prevalent in the Established church, which is properly called "broad," in distinction from "high" or "low" churchmanship. But it should always be borne in mind that the difference between the Broad Church party and the other two is less with reference to the doctrine of the Church as an institution than with reference to theology proper. It is in the field of doctrinal belief that breadth is most apparent. The members of this school were strongly influenced by the writings of Coleridge and by modern German theology. They were acquainted with the advancing scientific investigation and biblical study of their time. Maurice is perhaps best known as the theologian, Kingsley as the practical worker and writer, Robertson as the preacher, and Stanley as the historical writer of the group. In religious aim and method they are akin to certain other liberal leaders of the English church in the nineteenth century, such as Archbishop Whately and the writers of "Essays and Reviews" (q.v.). As champions of an earnest spiritual faith, Christian yet free, the Broad Churchmen have exercised an influence far beyond the limits of their own communion, and their writings have been read not only in Great Britain and America, but also upon the continent of Europe. Consult John Tulloch,

Movements of Religious Thought in Britain during the Nineteenth Century (London, 1885); John Hunt, *Religious Thought in England in the Nineteenth Century* (London, 1896); Cornish, *The English Church in the Nineteenth Century* (London, 1910); and the lives of Arnold, Maurice, Kingsley, Robertson, and Stanley.

BROADHEAD, GARLAND CARR (1827-). An American geologist, born near Charlottesville, Albemarle Co., Va. He studied at the University of Missouri and at the Western Military Institute in Kentucky. From 1871 to 1873 he was assistant State Geologist of Missouri and from 1873 to 1875 was State Geologist. He was a member of the jury on geology at the Philadelphia Centennial Exposition and in 1881 was a special agent of the tenth census for rendering a report on the quarrying industry of Missouri and Kansas. From 1884 to 1902 he was a member of the Missouri River Commission. For 10 years, beginning in 1887, he was professor of geology and mineralogy at the University of Missouri. It was he who gave the name to the Ozark series and to the Ozark Plateau. He became known as an authority on the coal measures of Missouri, on which he prepared a contribution to the *Transactions* (vol. ii, 1868) of the St. Louis Academy of Science. He also wrote a valuable report for nine counties of central Illinois in vol. iv, *Illinois Geological Survey Reports; Geological Survey of Missouri Iron Ores and Coal Fields* (1873); *Geological Survey of Missouri* (1873-74).

BROAD-HEADED SNAKE. See DEATH ADDER.

BROADHURST, GEORGE H. (1866-). An American playwright. He is author of many successful plays and musical comedies, including: *What Happened to Jones*, *Why Smith Left Home*, *The Wrong Mr. Wright*, *A Fool and his Money*, *The Crown Prince*, *The Man of the Hour*, *The Mills of the Gods*, *Bought and Paid For*, and the *Duke of Duluth* and *Nancy Brown*, musical comedies. *To-Day*, a play by Broadhurst and A. S. Schomer, was produced in New York in 1913.

BROADHURST, HENRY (1840-1911). An English legislator and labor organizer. The son of a journeyman stonemason, he began at 14 to follow his father's trade and continued in it until 1872, when a lockout in the building trades brought him to the front as a labor leader. In 1875 he became secretary of the Labor Representation League. He was especially prominent in English labor movements and in 1876 was secretary of the Parliamentary committees of the Trades Union Congress. In 1880 he was elected to Parliament and continued as a member except for an interval of a year and a half until his resignation in 1906. He became Undersecretary to the Home Office in 1886, and served on various commissions appointed to investigate labor questions. His publications include *Handy Book on Leasehold Emfranchisement* (1885), and his autobiography (1901).

BROADMOUTH, or **BROADBILL**. One of about a dozen species of small birds, distributed from the Himalayas to the Philippines, and characterized by excessive breadth of beak. They constitute a family, Eurylemidae, the affinities of which have been long disputed, but the best opinion now regards it as worthy of an order Eurylemiformes, which, with that of the lyre bird, comes close to the Passeriformes. Seven genera and 16 species are known. These birds

are no larger than sparrows, inhabit the woods in small flocks, are brilliant in plumage, but songless and lethargic, and are mainly frugivorous; but two species (of the genus *Calyptomena*) are insect eaters. These last "are remarkable for their rich green plumage and the way in which the frontal feathers project upward and forward, so as to . . . form a disk-like prominence." See plate of LYRE BIRD, etc.

BROAD RIVER. A stream of North and South Carolina, rising in the Blue Ridge and joining with the Saluda to form the Congaree (Map: South Carolina, C 2). The city of Columbia is at the junction of the two rivers. The country around Broad River is exceedingly fertile and productive. The stream is about 220 miles long and navigable for small vessels about 141 miles above Columbia.

BROADS, THE. An extensive marshy tract in the eastern part of Norfolk Co., England. It is traversed by numerous navigable channels and is a favorite resort of hunters.

BROADSIDE, or **BROADSHEET**. A variety of pamphlet, consisting normally of a single large sheet, printed on one side only and most frequently without division into columns. The broadside flourished chiefly in England and was in use from the invention of printing for royal proclamations, papal indulgences, and similar documents. It made a considerable figure throughout western Europe, about the middle of the sixteenth century, in times of political agitation. In England it was very largely used for popular ballads, which were hawked about the streets. During the first 10 years of Elizabeth's reign the names of no less than 40 ballad printers appear in the Stationers' Registers; but comparatively few specimens have been preserved from the reigns of the Tudor sovereigns or of James I. The broadside, as representing an outburst of popular feeling, was more commonly employed during the Civil War and seems to have reached its culminating point in the time of James II, when even poems by Dryden were printed and circulated on broadsides. From that period, with the increase in the number of newspapers and the liberty of the press, it gradually died out, though still numerous even under the Georges. The collection of these sheets has always been a favorite pursuit among antiquarians, though never so popular as in recent years. Robert Burton, the author of the *Anatomy of Melancholy*, was one of the earliest collectors. John Selden made a considerable collection of broadside ballads, which passed at his death to Pepys; the diarist had 1800 English ballads, which, bound in five folio volumes, are now in the library of Magdalene College, Cambridge. One of the most famous collections is that known by the name of the Duke of Roxburghe, now in the British Museum, gathered chiefly by Robert Harley, Earl of Oxford, and including 2048 broadsides, bound in three volumes. In 1898 Lord Crawford had, at Haigh Hall, Wigan, something like 19,000. For a minute and scholarly description of the English part of these, consult *Bibliotheca Lindesiana* (Aberdeen, 1898). The word "broadside" in America is often applied to roughly printed excerpts from magazines sent out in advance to the newspapers for comment.

BROADSTAIRS (formerly *Bradstowe*). A town on the coast of Kent, England, about 3 miles southeast of Margate (Map: England, II 5). It is a popular summer resort, and has a

small pier built early in the sixteenth century, and an archway leading to the shore supposed to have been erected in 1540. Dickens visited Broadstairs frequently between 1837 and 1851 and described it in a sketch entitled *Our English Watling-Place*. Pop., 1891, 5234, 1901, 6460, 1911, 8929.

BROADSWORD A broad-bladed sword for cutting only, not for stabbing, and therefore not sharp at the point like a sabre.

BROAD'US, JOHN ALBERT (1827-95) An American clergyman, born in Culpeper Co., Va. He graduated at the University of Virginia in 1850, was professor of ancient languages there from 1851 to 1853, and during this period was also pastor of the Baptist Church in Charlottesville. In 1859 he became professor of New Testament interpretation and homiletics in the Southern Baptist Theological Seminary, which had just been established in Greenville, S. C., but is now located in Louisville, Ky. For many years preceding his death he was president of the institution. He wrote *College Education for Men of Business* (1875), *A Treatise on the Preparation and Delivery of Sermons* (23d ed., 1898).

BROADWAY The principal thoroughfare of New York, and one of the most important business streets in the world. Beginning at Bowling Green, near the southern extremity of Manhattan Island, it runs north to Central Park, and is thence continued by the extension formerly called the Boulevard, now a part of Broadway, to the northern part of the island. Broadway is practically a continuous road to Albany and bears the same name in many of the Hudson River towns through which it passes. The first grant of a lot on Broadway was made in 1643 to Martin Kregier, whose tavern, at the present No. 9, later became Burns's Coffee House and subsequently the Atlantic Gardens. In the early part of the nineteenth century various portions of Broadway, then only some two miles long, became in turn the fashionable residence section of the city. Now the street below and above Central Park is given up almost exclusively to business. Below Chambers Street are most of the offices of great corporations. Then follows the wholesale dry-goods district, which at Eighth Street gives way to the shopping district, recently removed to Thirty-fourth Street and beyond, while Forty-second Street is the centre of the theatre district. From Fifthth Street north the street is more and more given over to apartment houses. The rapid-transit subway of New York throughout part of its course runs under the surface of Broadway. Consult Jenkins, *The Greatest Street in the World* (New York, 1911), and Kerfoot, *Broadway* (Boston, 1911).

BROAD-WINGED HAWK See BUZZARD.
BROB'DINGNAG A strange land described in Swift's *Gulliver's Travels* (1726). The inhabitants of this wonderful country are represented as giants, about "as tall as an ordinary spire-steeple," and everything else is on the same enormous scale. The original satire of the work is now largely forgotten and the adjective *brobdingnagian* has arisen as a synonym of "gigantic." The name is frequently, though incorrectly, spelled *Brobdingnag*. Swift wrote a mock letter from Captain Gulliver to his cousin Sympson, in which complaint was made that Brobdingnag had been wrongly printed for Brobdingrag; but this was only a feint to mystify the public. See SWIFT, JONATHAN.

BROCA, PAUL (1824-80) A French anthropologist, born at Sainte-Foy-la-Grande, Gironde. He studied at the Communal College of Sainte-Foy and the Ecole Polytechnique and Faculté de Médecine of Paris, became in 1846 assistant in anatomy to the Faculté, in 1848 prosecutor, and subsequently professor of surgical pathology. At various times he also held appointments as surgeon to important hospitals, including La Pitié and La Salpêtrière. In 1847, when he was connected as medical assistant with a commission for the preparation of a report on excavations in the church of the Celestins, he began a thorough study of anthropology. In 1859, amid difficulties caused by the hostility or indifference of other scientists and by the opposition of the government, which suspected political plots, he founded the Anthropological Society of Paris. From the formation of this society, officially authorized in 1861, modern anthropological science may be said to date. Broca established in 1872 the *Revue d'Anthropologie*, among the foremost periodicals of its class, in which many of his own works originally appeared. Finally he founded, in 1876, at Paris, the well-known Ecole d'Anthropologie, equipped with laboratories, a library, and a well-stocked museum. Among its numerous courses was one by himself on the comparative anatomy of the primates. The society, the school, and the laboratories are now known under the collective title of the Anthropological Institute. During all this time Broca was constantly occupied with researches, many important results of which were published in *Instructions générales pour les recherches anthropologiques* (1865) and *Instructions craniologiques et craniométriques* (1875). In 1861 he made and announced his noteworthy discovery of the seat of articulate speech in the third convolution of the left frontal lobe of the brain, since commonly called the "convolution of Broca." Disease in this convolution, cutting off the blood supply from it, or severing the fibres that lead from it to other parts of the brain, causes inability to make the effort needed to pronounce words or to read aloud. (See APHASIA, NERVOUS SYSTEM.) The importance of Broca's contributions to anthropology cannot be overestimated.

Broca's activities were many-sided. He was one of the three directors of public assistance through the Franco-Prussian War, and from 1880 a permanent Senator. He was also interested in literature and aesthetics and has been described as an attractive raconteur and conversationalist. His friend and colleague, M. Jacques Bertillon, is quoted as having said of him, "Rarely has there been a mind so active, so equally open to all kinds of knowledge, and so equally fond of all kinds." His energy as both teacher and writer was truly enormous. Besides numerous memoirs on a wide range of subjects, and an extensive list of contributions to the *Bulletins* of the Anthropological Society and the *Revue d'Anthropologie*, he published the celebrated work, *Des anomalies et de leur traitement* (1856), *L'Ethnologie de la France* (1859), *Recherches sur l'hybridité animale en général et sur l'hybridité humaine en particulier* (1860), *Traité des tumeurs* (1865-69), *Mémoires sur les caractères physiques de l'homme préhistorique* (1869), and *Mémoires d'anthropologie* (4 vols., 1871-83). Consult *Correspondance de Paul Broca* (2 vols., Paris, 1886). A statue of him by Choppin was placed

in the Ecole de Médecine in 1887. Consult the biography by Pozzi (Paris, 1880).

BROCADE' (Sp. *brocado*, It. *broccato*; cf. Fr. *brocher*, to stitch, embroider). A woven fabric of silk on which figures are formed by the threads of the warp or filling being raised so as to produce the required pattern. Brocades have long been manufactured in Oriental countries, and in Europe since the thirteenth century. The earlier and richer brocades were composed in part of gold and silver threads, and the name is often applied to the simplest silk fabrics thus enriched.

BROCAGE, brók'aj, **BROKERAGE**. In general the business of procuring contracts for others. (See **BROKER**.) Specifically, the business of bringing about marriage contracts. This business is deemed unlawful, as being contrary to public policy, and as a consequence the law refuses to enforce agreements for the services of a marriage broker and denies to such a broker any legal right to the compensation agreed to be paid him therefor. In a recent case in England it has even been held that a contract to introduce a person to various persons of the opposite sex with a view to marriage was illegal and that money paid under such a contract might be recovered. (Hermann v. Charlesworth [1905], 2 K. B. 123.)

BRO'CATEL. A coarse fabric of silk and wool or silk and cotton with figured designs resembling those of brocade, used largely for tapestry and upholstery. The term is also applied to a damask satin in which the satin ornamentation is on a less lustrous ground of the same color.

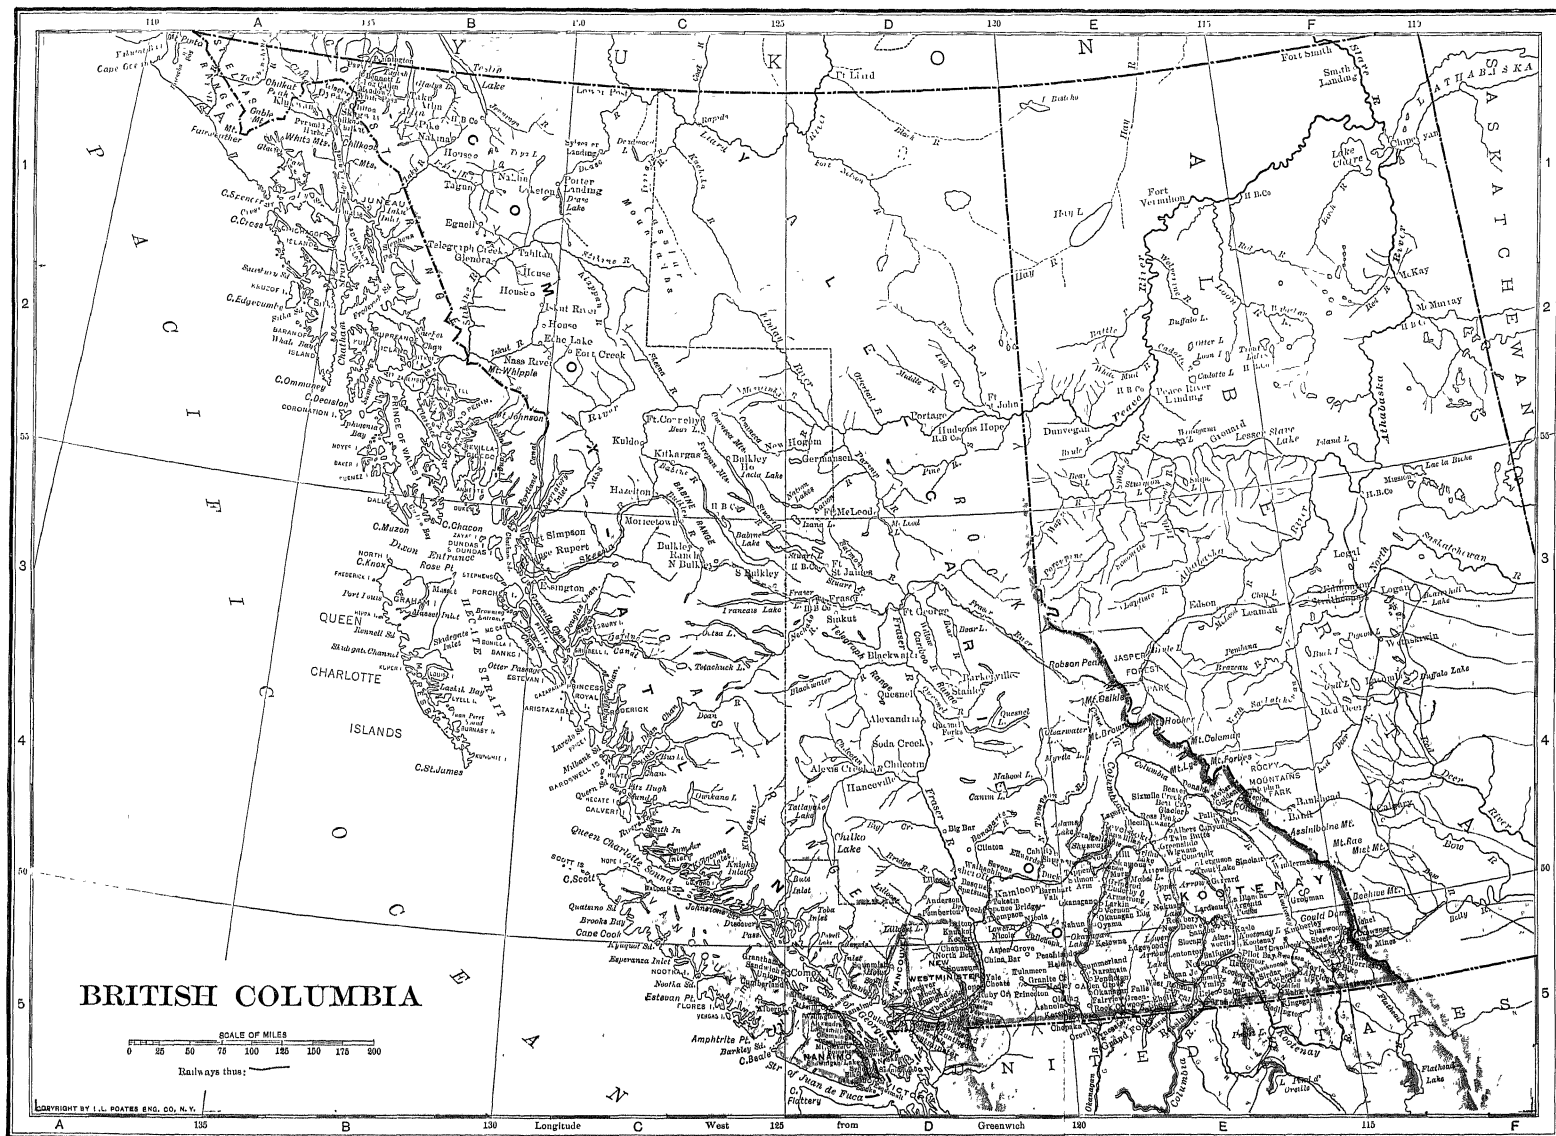

BROCCHI, brók'kí, GIOVANNI BATTISTA (1772-1826). An Italian mineralogist and geologist. He was born in Bassano, studied in Pisa, Rome, and Venice, and was professor of botany in Brescia, but devoted himself largely to geology. In 1809 he was made inspector of mines in Milan. During his travels through Italy he made many observations regarding Tertiary fossils, and his "Fossil Conchology," published in 1814, is a recognized masterpiece of paleontological literature. In 1823 he went to Egypt, and two years later Mehmet Ali made him one of a commission to organize the provinces of Senar; but he soon fell a victim to the climate of Khartum. His works include: *Trattato mineralogico e chimico sulle miniere di ferro del dipartimento del Meila* (2 vols., 1807); *Memoria mineralogica sulla Valle di Fassa nel Tirolo* (1811); *Conchologia fossile subappennina con osservazioni geologiche* (2 vols., 1814); *Dello stato fisico del suolo di Roma* (1820).

BROCCOLI. A variety of cauliflower (q.v.). **BROCHANTITE**. A basic sulphate of copper commonly found in acicular orthorhombic crystals or drusy crusts of an emerald-green or blackish-green color and vitreous lustre. It is mostly found associated with other copper minerals, of which it is often an alteration product.

BROCK, SIR ISAAC (1760-1812). An English soldier, known as the "Hero of Upper Canada." He was born in Guernsey, entered the army as an ensign at the age of 15, and rose by purchase, in accordance with the custom of the time, to the rank of lieutenant colonel (1797). He led his regiment in the North Holland expedition in 1799, when he was wounded at Egmont-op-Zee, and then fought in the naval battle of Copenhagen. He served in Canada from 1802 to 1805, when he went to England on leave; but

returned in 1806, on account of the threatened hostilities between England and the United States, and commanded the Quebec garrison until 1810. He was then put in command of all troops in Upper Canada, and was soon afterward appointed provisional Lieutenant Governor of the province. In 1811 he was promoted major general. Upon the outbreak of the War of 1812 he made energetic preparations to repel an invasion by an American force under Gen. William Hull, and on Aug. 16, 1812, with a small force of Indians and whites, he captured Detroit. (See HULL, WILLIAM.) For this he was made an extra Knight of the Bath. On October 13, during the American attack upon Queenston, he fell mortally wounded at the head of his troops, his last words being, "Never mind me; push on the York Volunteers." Soon afterward a monument to him was erected in St. Paul's, London, with money appropriated by the House of Commons. In 1824 his remains were removed from a bastion of Fort George to Queenston Heights, where a monument costing £3000 was erected by the Provincial Legislature. This monument was destroyed by a fanatic in 1840; and in July, 1841, a mass meeting of more than 8000 people, presided over by the Lieutenant Governor of Upper Canada, voted £5000 for the present monument, a tall shaft surmounted by a statue of Brock. Consult Tupper (Brock's nephew), *Life and Correspondence of Sir Isaac Brock* (London, 1845; 2d ed., much enlarged, 1847), and Lady M. Edgar, *General Brock* (Toronto, 1904).

BROCK, SIR THOMAS (1847-). A prominent English sculptor. He was born in Worcester and studied principally in London as a pupil and assistant of J. H. Foley and afterward at the Royal Academy. After Foley's death Brock was commissioned to complete his unfinished works; among others, the monument to Daniel O'Connell in Dublin and Lord Canning in Calcutta. Brock's art, like that of his master, Foley, was a protest against the prevalent classicism in British art. But he allowed the leavening influence of French sculpture to modify and develop his style to a height never attained by Foley. Though not always original, his art is invariably dignified and refined. Among the best known of his statues are those of Robert Raikes (Thames Embankment, London); the bronze equestrian statue of the Black Prince (City Square, Leeds); the seated marble statue of Bishop Philpott in Worcester Cathedral; the admirable statue of Thomas Gainsborough with palette and brushes (Tait Gallery, London); the recumbent statue of Lord Leighton in St. Paul's, and Sir Henry Irving (1910). After executing a number of statues and busts of Queen Victoria, he was in 1901 commissioned, as the best portraitist of the day, to prepare the sculptural designs of the national monument to the Queen in front of Buckingham Palace, upon which he was still working in 1914, by far the largest and most ambitious monument in London. Among the best examples of his purely ideal figure work are "Ive," "A Moment of Peril" (both in the National Gallery), and the graceful marble called "The Genius of Poetry." Brock was elected associate of the Royal Academy in 1883, member in 1891, and was knighted in 1911; he is also honorary member of the Société des Artistes Français. Consult Spielmann, *British Sculpture of To-Day* (London, 1901).

3913
